

REST APIs - REST Web Services

You will learn how to ...

- Create REST APIs / Web Services with Spring
- Discuss REST concepts, JSON and HTTP messaging
- Install REST client tool: Postman
- Develop REST APIs / Web Services with **@RestController**
- Build a CRUD interface to the database with Spring REST

Practical Results

- Introduction to Spring REST development
- Not an A to Z reference ... for that you can see [Spring Reference Manual](#)

<https://projects.spring.io/spring-framework/>

Business Problem

- Build a client app that provides the weather report for a city
- Need to get weather data from an external service

Application Architecture

Questions

- How will we connect to the Weather Service?
- What programming language do we use?
- What is the data format?

Answers

- How will we connect to the Weather Service?
- We can make REST API calls over HTTP
- REST: REpresentational State Transfer
- Lightweight approach for communicating between applications

Answers

- What programming language do we use?
- REST is language independent
- The **client** application can use **ANY** programming language
- The **server** application can use **ANY** programming language

Answers

- What is the data format?
 - REST applications can use any data format
 - Commonly see XML and JSON
 - JSON is most popular and modern
 - JavaScript Object Notation

Possible Solution

- Use online Weather Service API provided by: openweathermap.org
- Provide weather data via an API
- Data is available in multiple formats: JSON, XML etc ...

Call Weather Service

- The API documentation gives us the following:
 - Pass in the latitude and longitude for your desired location

```
api.openweathermap.org/data/<apiVersion>/onecall?lat={theLatitude}&lon={theLongitude}
```

**Pass the
latitude and longitude
of the city**

Response - Weather Report

- The Weather Service responds with JSON

```
{  
  ...  
  "temp": xxx,  
  "feels_like": yy,  
  "humidity": zz,  
  ...  
}
```

Condensed
version

Multiple Client Apps

Remember:
REST calls can be made over HTTP
REST is language independent

My
Weather
Spring MVC

My
Weather
C# App

My
Weather
iPhone App

Weather
Service
(external)

Currency Converter App

Movie Tickets App

Customer Relationship Manager (CRM) App

We will create
this code using
Spring REST
(SERVER)

What do we call it?

REST API

**REST
Web Services**

REST Services

RESTful API

**RESTful
Web Services**

RESTful Services

Generally, all mean the SAME thing

What do we call it?

REST API

**REST
Web Services**

REST Services

RESTful API

**RESTful
Web Services**

RESTful Services

Generally, all mean the SAME thing

JSON Basics - Syntax

What is JSON?

- JavaScript Object Notation
- Lightweight data format for storing and exchanging data ... plain text
- Language independent ... not just for JavaScript
- Can use with any programming language: Java, C# , Python etc ...

**JSON is just
plain text
data**

Simple JSON Example

- Curley braces define objects in JSON
- Object members are name / value pairs
 - Delimited by colons
- Name is **always** in double-quotes

JSON Values

- Numbers: no quotes
- String: in double quotes
- Boolean: **true**, **false**
- Nested JSON object
- Array
- **null**

```
{  
  "id": 14,  
  "firstName": "Mario",  
  "lastName": "Rossi",  
  "active": true,  
  "courses" : null  
}
```

Nested JSON Objects

```
{
  "id": 14,
  "firstName": "Mario",
  "lastName": "Rossi",
  "active": true,
  "address" : {
    "street" : "100 Main St",
    "city" : "Philadelphia",
    "state" : "Pennsylvania",
    "zip" : "19103",
    "country" : "USA"
  }
}
```

JSON Arrays

```
{  
  "id": 14,  
  "firstName": "Mario",  
  "lastName": "Rossi",  
  "active": true,  
  "languages" : ["Java", "C#", "Python", "Javascript"]  
}
```

Array

REST HTTP Basics

REST over HTTP

- Most common use of REST is over HTTP
- Leverage HTTP methods for CRUD operations

HTTP Method	CRUD Operation
POST	<u>C</u> reate a new entity
GET	<u>R</u> ead a list of entities or single entity
PUT	<u>U</u> pdate an existing entity
DELETE	<u>D</u> eleate an existing entity

HTTP Messages

HTTP Request Message

- Request line: the HTTP command
- Header variables: request metadata
- Message body: contents of message

HTTP Request Message

HTTP Response Message

- Response line: server protocol and status code
- Header variables: response metadata
- Message body: contents of message

HTTP Response Message

Response line

Header variables

Message body

HTTP Response - Status Codes

Code Range	Description
100 - 199	Informational
200 - 299	Successful
300 - 399	Redirection
400 - 499	Client error
500 - 599	Server error

401 Authentication Required
404 File Not Found

500 Internal Server Error

MIME Content Types

- The message format is described by MIME content type
 - Multipurpose Internet Mail-Extension
- Basic Syntax: `type/sub-type`
- Examples
 - `text/html`, `text/plain`
 - `application/json`, `application/xml`, ...

Client Tool

- We need a client tool
- Send HTTP requests to the REST Web Service / API
- Plenty of tools available: curl, Postman, etc ...

Postman

Free
developer
plan

www.getpostman.com

Install Postman Now

www.getpostman.com

Choose your platform:

Postman for Mac
for OS X Yosemite or later

Download

Postman for Windows
for Windows 7 or later

x64  Download

Postman for Linux

Postman Demo

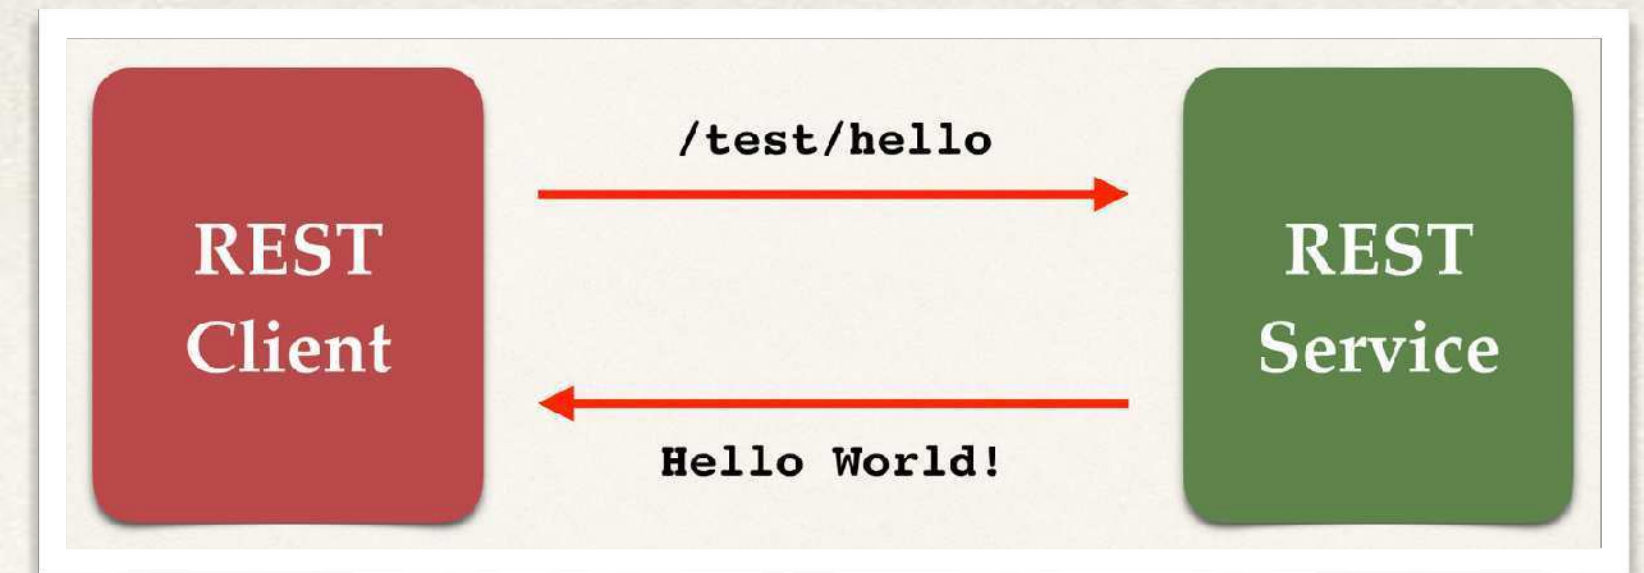

Spring REST Controller

Spring REST Hello World

Spring REST Controller

Adds REST support

```
@RestController
@RequestMapping("/test")
public class DemoRestController {

    @GetMapping("/hello")
    public String sayHello() {
        return "Hello World!";
    }
}
```

Access the REST endpoint at
/test/hello

Returns content to
client

Testing with REST Client - Postman

Access the REST endpoint at
`/test/hello`

The response

Testing with REST Client - Web Browser

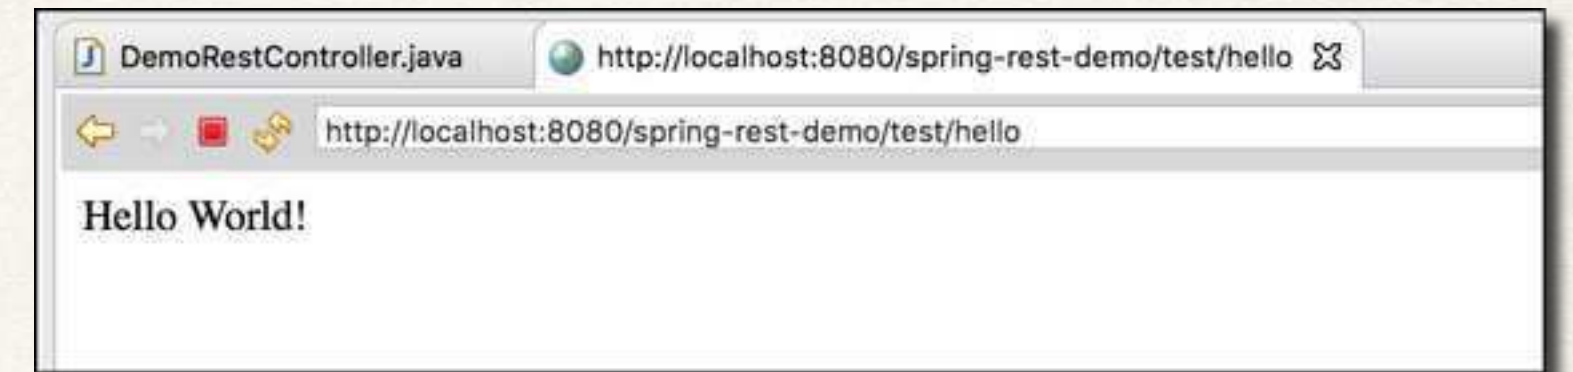

Access the REST endpoint at
`/test/hello`

The response

Web Browser vs Postman

- For simple REST testing for GET requests
 - Web Browser and Postman are similar
- However, for advanced REST testing: POST, PUT etc ...
 - Postman has much better support
 - POSTing JSON data, setting content type
 - Passing HTTP request headers, authentication etc ...

Spring REST Controller - Dev Process

Development Process

Step-By-Step

1. Add Maven dependency for Spring Boot Starter Web
2. Create Spring REST Service using @RestController

Step 1: Add Maven Dependency

File: pom.xml

```
<!-- Add Spring Boot Starter Web -->  
<dependency>  
  <groupId>org.springframework.boot</groupId>  
  <artifactId>spring-boot-starter-web</artifactId>  
</dependency>
```

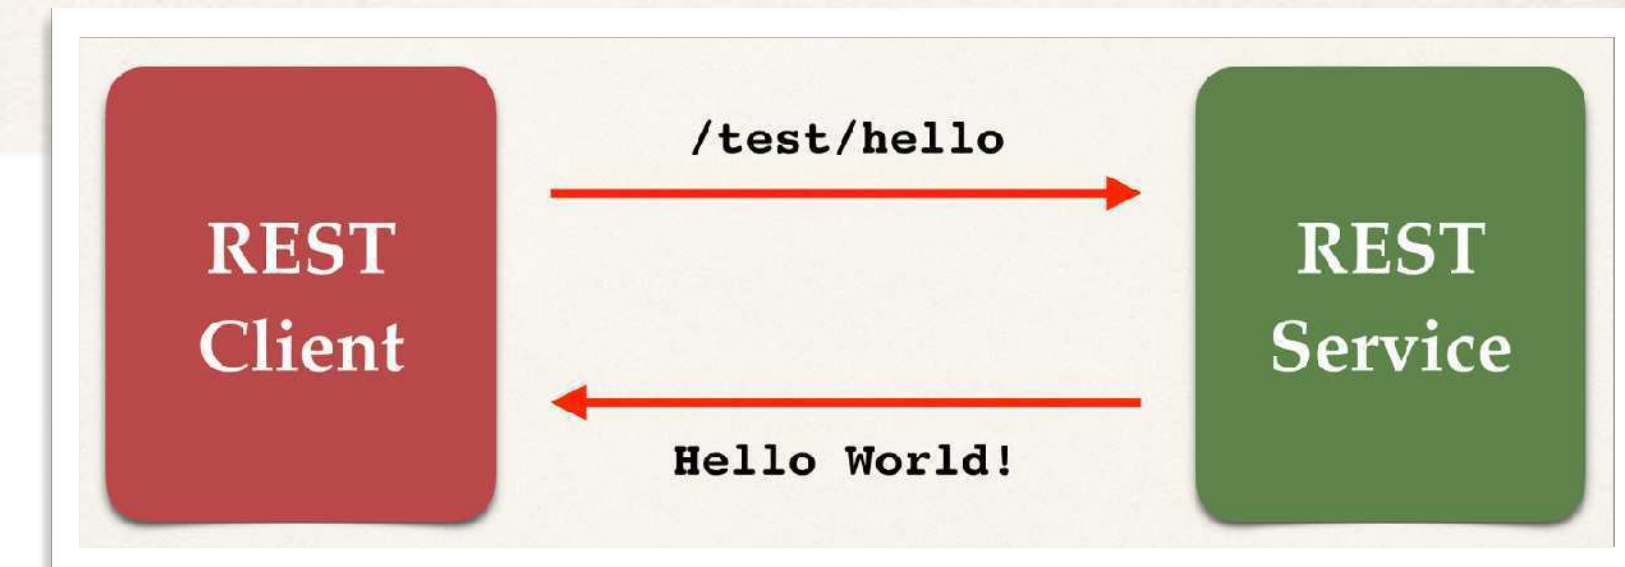

**At Spring Initializr website,
can also select the “Web” dependency**

Step 2: Create Spring REST Service

```
@RestController
@RequestMapping("/test")
public class DemoRestController {

    @GetMapping("/hello")
    public String sayHello() {
        return "Hello World!";
    }

}
```

Handles HTTP GET requests

Java JSON Data Binding

Java JSON Data Binding

- Data binding is the process of converting JSON data to a Java POJO

JSON Data Binding with Jackson

- Spring uses the **Jackson Project** behind the scenes
- Jackson handles data binding between JSON and Java POJO
- Details on Jackson Project:

<https://github.com/FasterXML/jackson-databind>

Jackson Data Binding

- By default, Jackson will call appropriate getter / setter method

```
{  
  "id": 14,  
  "firstName": "Mario",  
  "lastName": "Rossi",  
  "active": true  
}
```

Java
POJO

Student

JSON to Java POJO

- Convert JSON to Java POJO ... call setter methods on POJO

```
{  
  "id": 14,  
  "firstName": "Mario",  
  "lastName": "Rossi",  
  "active": true  
}
```

*Call
setXXX
methods*

Jackson will do
this work

Java
POJO

Student

JSON to Java POJO

Note: Jackson calls the setXXX methods
It does NOT access internal private fields directly

- Convert JSON to Java POJO ... call setter methods on POJO

```
{  
  "id": 14,  
  "firstName": "Mario",  
  "lastName": "Rossi",  
  "active": true  
}
```

Call setId(...)

Call setFirstName(...)

setLastName(...)

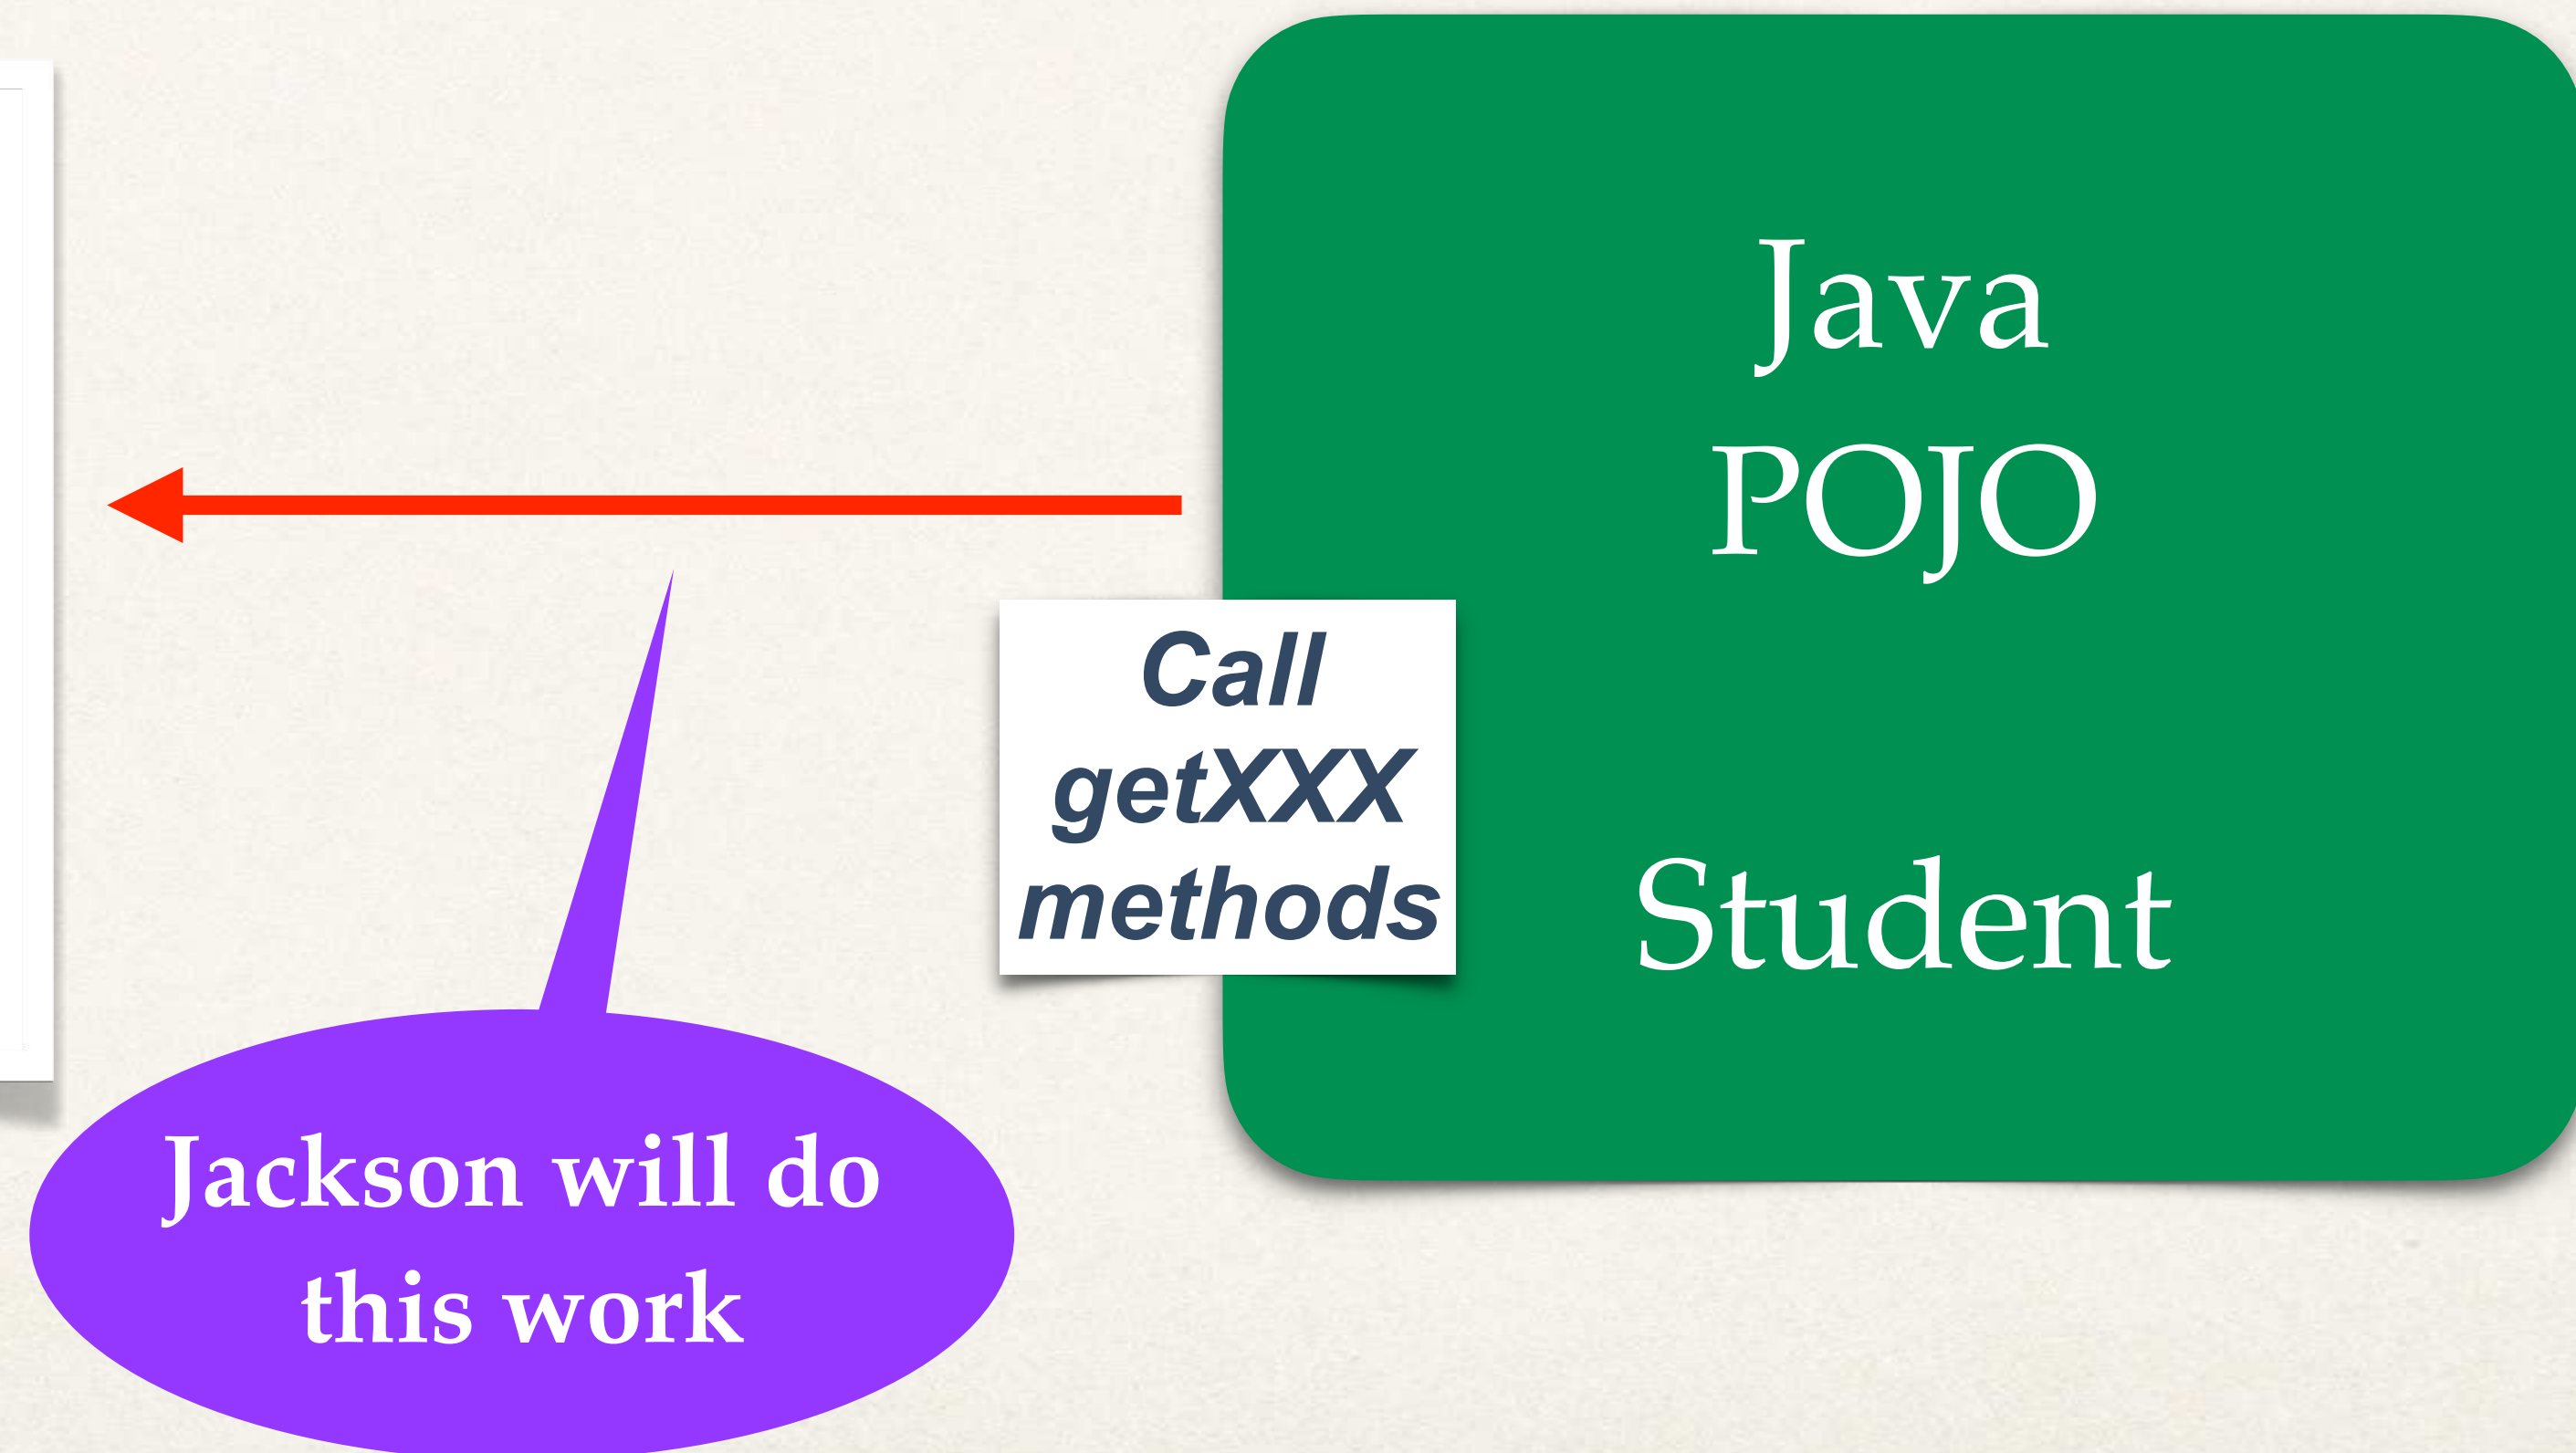

Jackson will do
this work

```
public class Student {  
  
    private int id;  
    private String firstName;  
    private String lastName;  
    private boolean active;  
  
    public void setId(int id) {  
        this.id = id;  
    }  
  
    public void setFirstName(String firstName) {  
        this.firstName = firstName;  
    }  
  
    public void setLastName(String lastName) {  
        this.lastName = lastName;  
    }  
  
    public void setActive(boolean active) {  
        this.active = active;  
    }  
  
    // getter methods  
}
```

Java POJO to JSON

- Now, let's go the other direction
- Convert Java POJO to JSON ... call getter methods on POJO

```
{  
  "id": 14,  
  "firstName": "Mario",  
  "lastName": "Rossi",  
  "active": true  
}
```

Spring and Jackson Support

- When building Spring REST applications
- Spring will automatically handle Jackson Integration
- JSON data being passed to REST controller is converted to POJO
- Java object being returned from REST controller is converted to JSON

**Happens
automatically
behind the scenes**

Spring REST Service - Students

Create a New Service

- Return a list of students

GET

/api/students

Returns a list of students

Spring REST Service

We will write
this code

REST
Client

`/api/students`

REST
Service

Web Browser
Or
Postman

```
[  
  {  
    "firstName": "Poornima",  
    "lastName": "Patel"  
  },  
  {  
    "firstName": "Mario",  
    "lastName": "Rossi"  
  },  
  {  
    "firstName": "Mary",  
    "lastName": "Smith"  
  }  
]
```

Convert Java POJO to JSON

- Our REST Service will return **List<Student>**
- Need to convert **List<Student>** to JSON
- Jackson can help us out with this ...

Spring Boot and Jackson Support

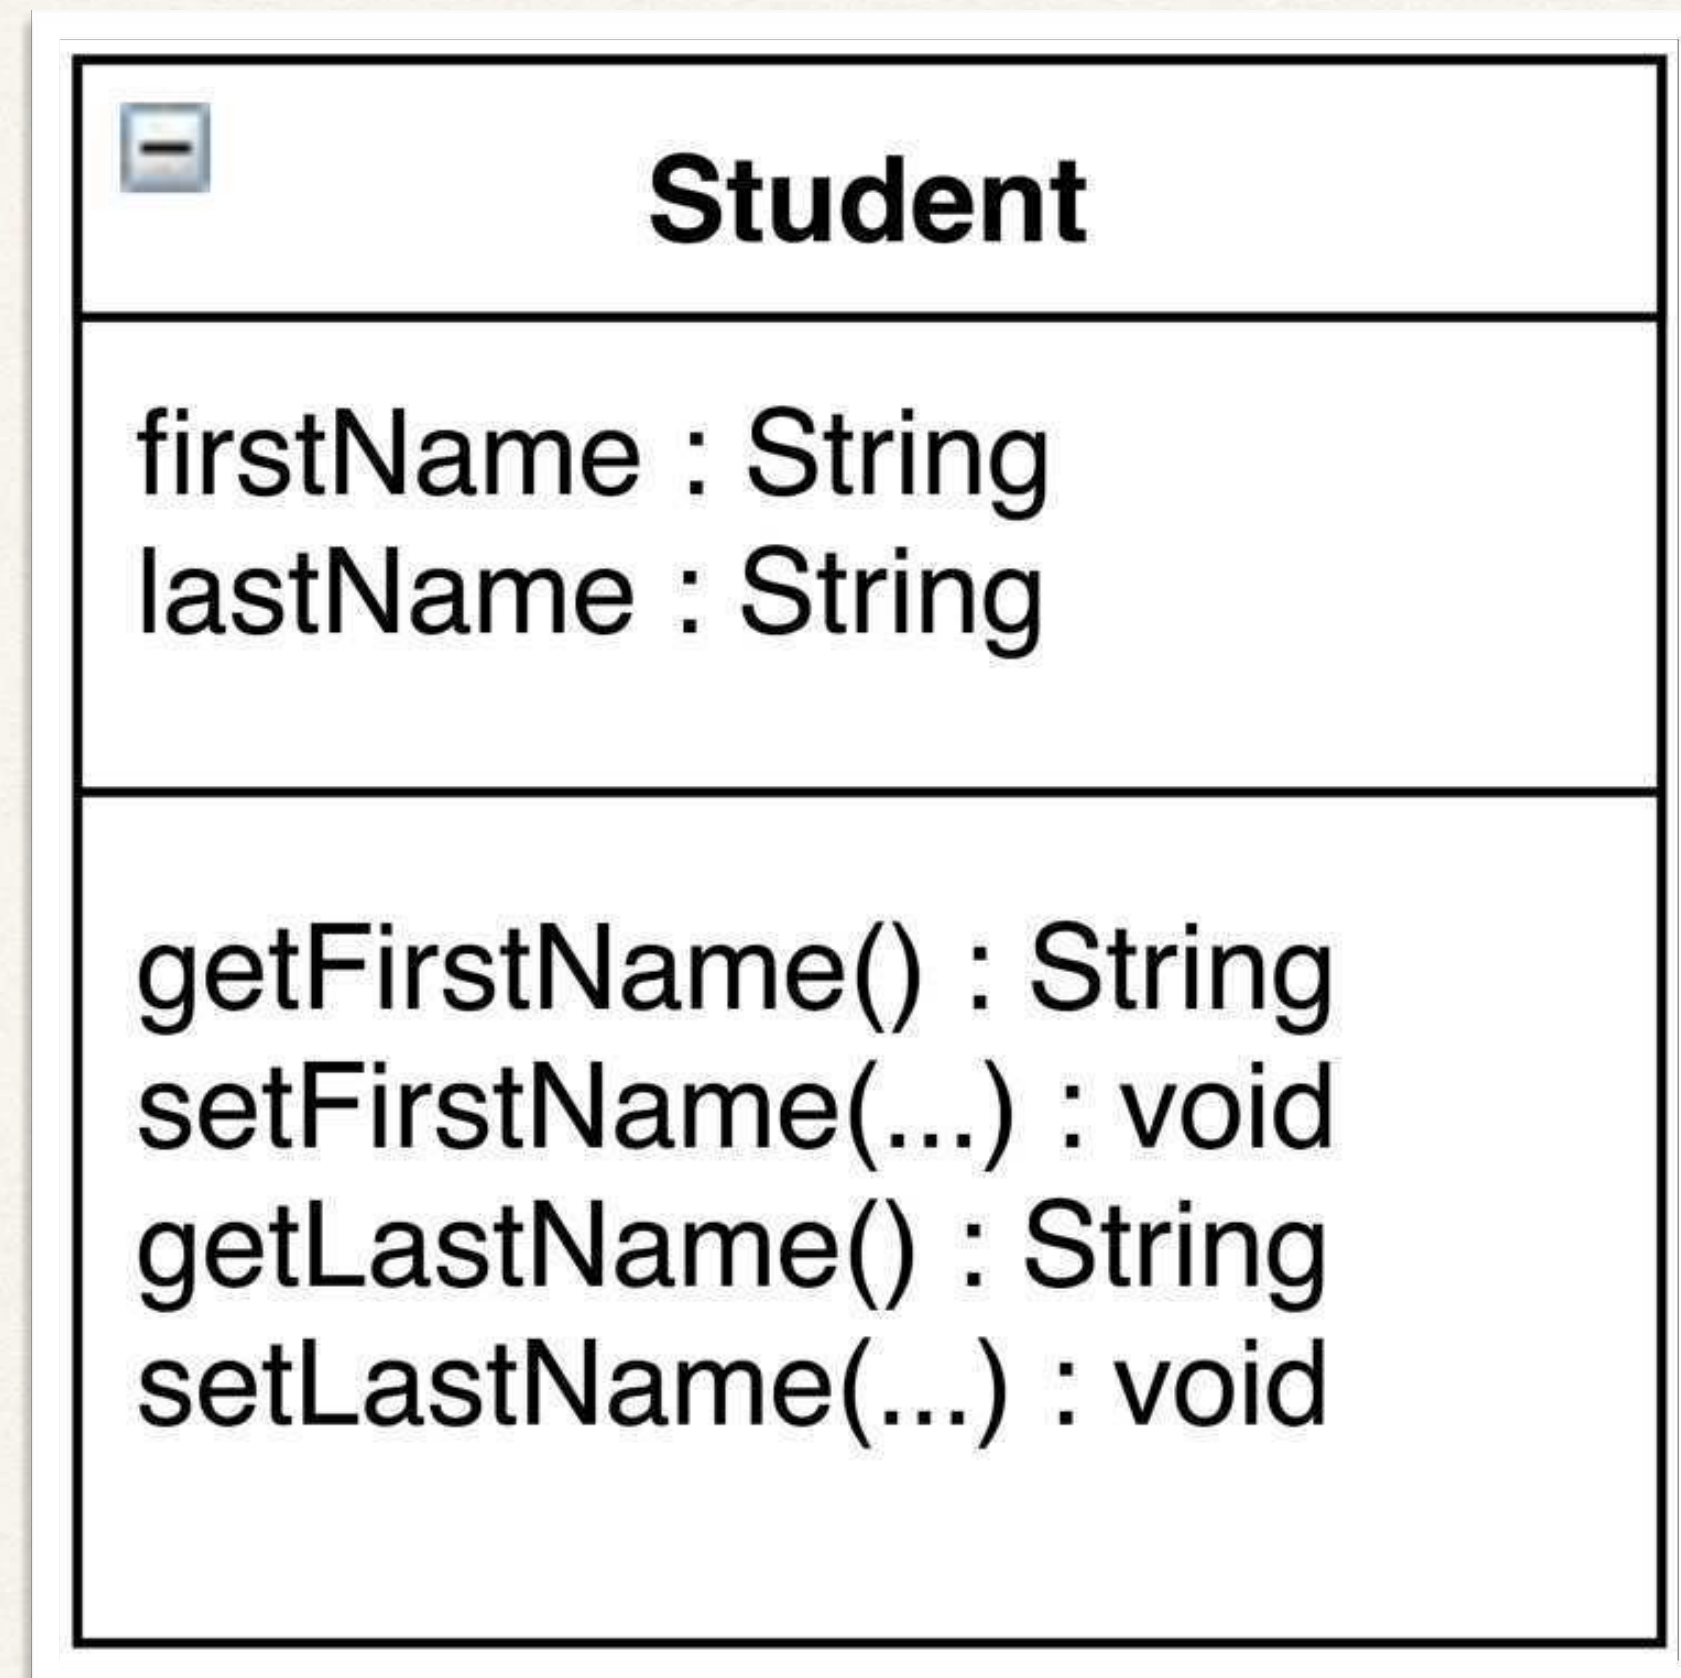

**Happens
automatically
behind the scenes**

- Spring Boot will automatically handle **Jackson** integration
- JSON data being passed to REST controller is converted to Java POJO
- Java POJO being returned from REST controller is converted to JSON

Student POJO (class)

Java
POJO

Student

Jackson Data Binding

- Jackson will call appropriate getter / setter method

Remember

```
{  
  "id": 14,  
  "firstName": "Mario",  
  "lastName": "Rossi",  
  "active": true  
}
```

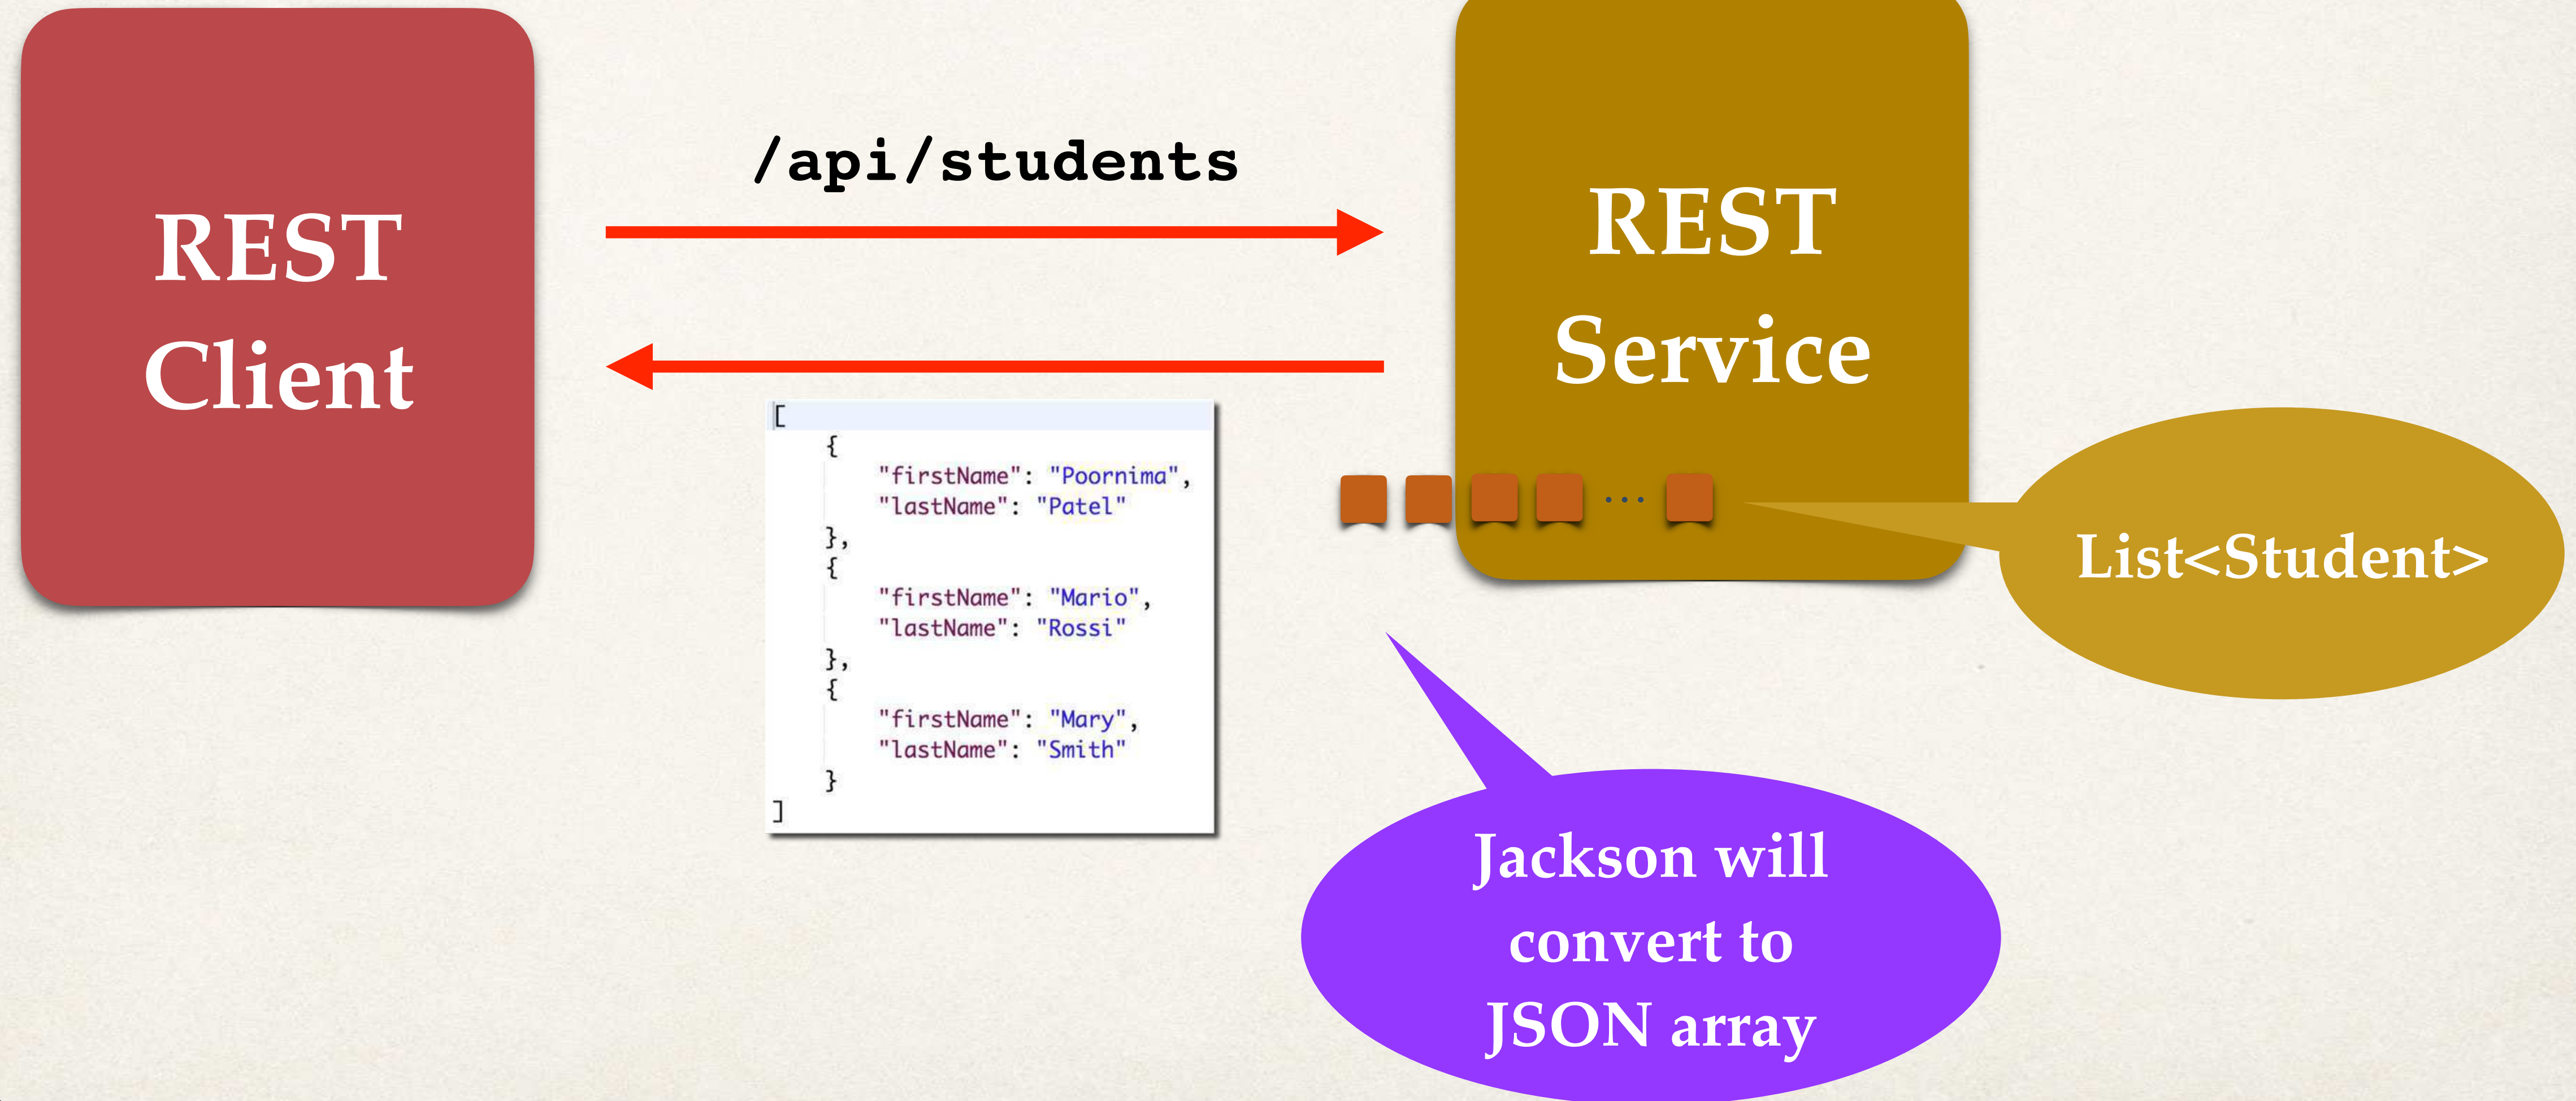

Jackson will do
this work

Java
POJO

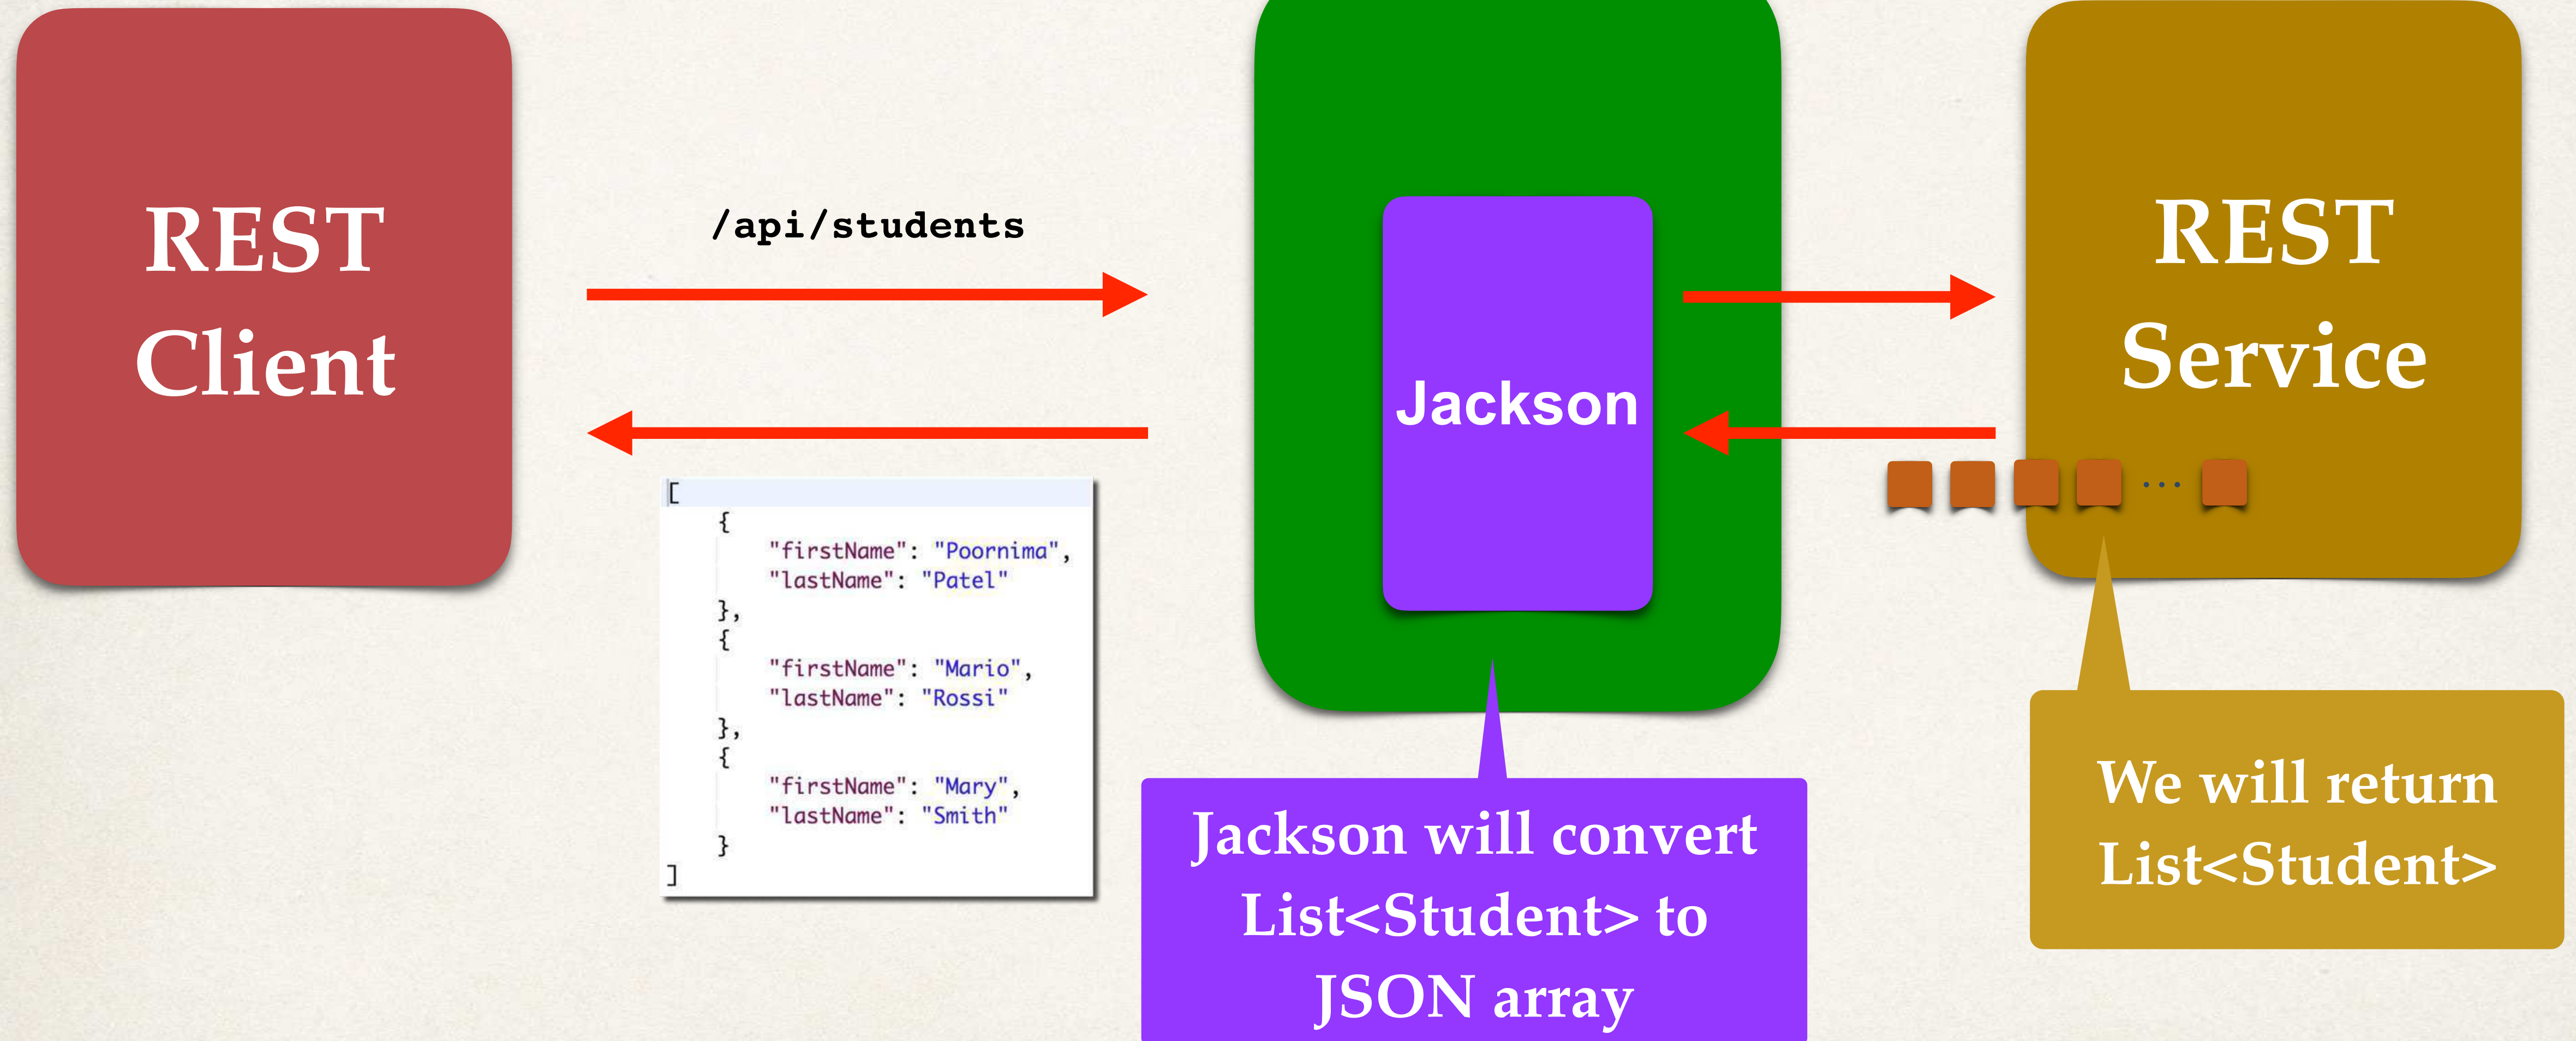

Student

Student
firstName : String lastName : String
getFirstName() : String setFirstName(...) : void getLastName() : String setLastName(...) : void

Spring REST Service

Behind the scenes

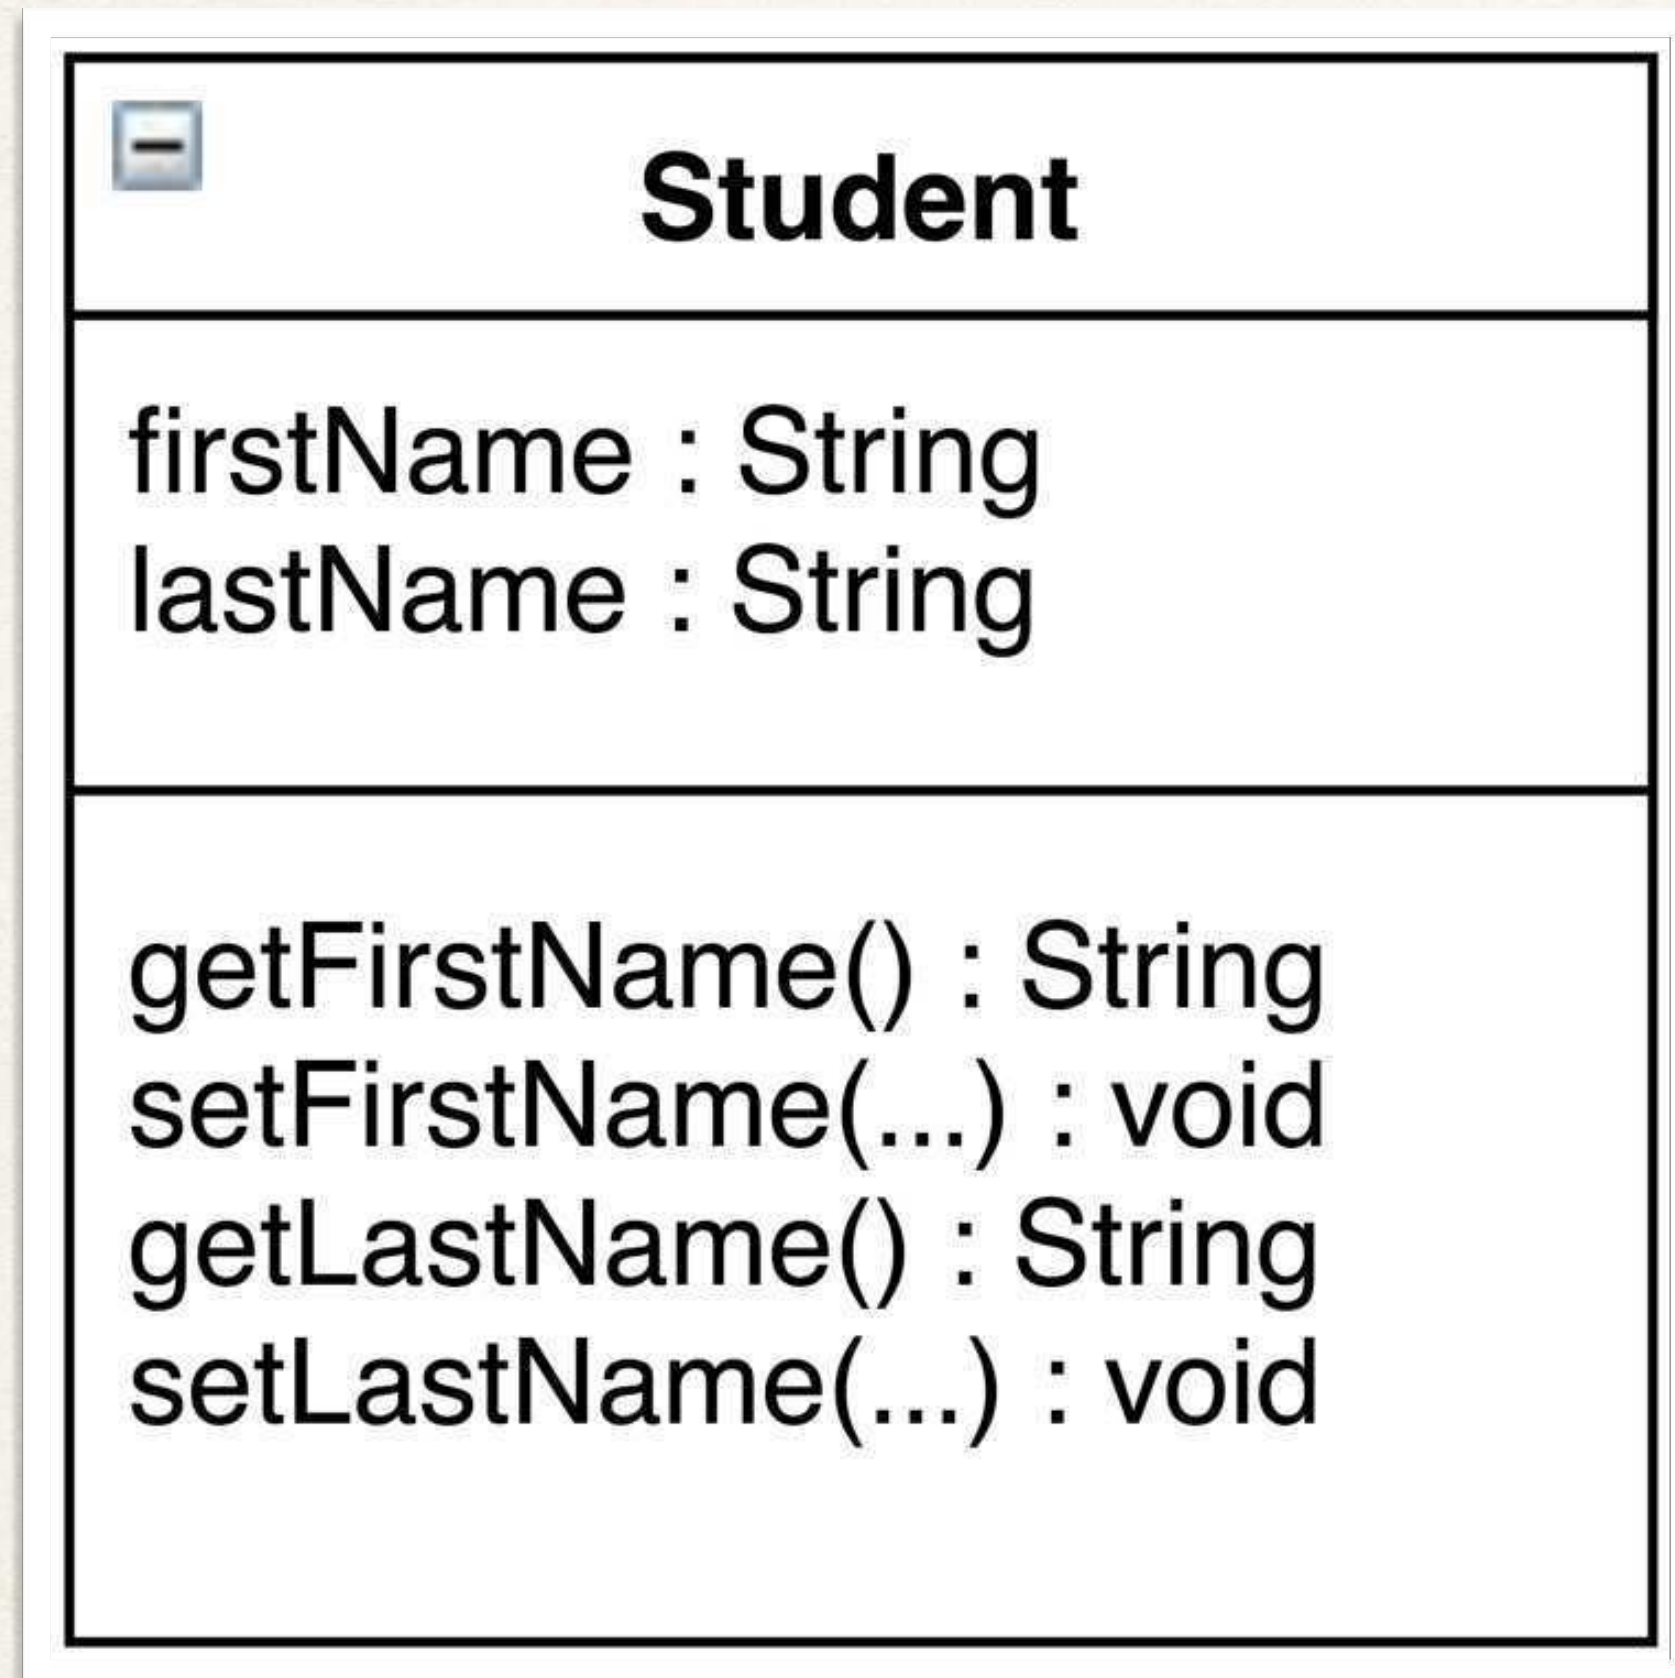

Development Process

Step-By-Step

1. Create Java POJO class for **Student**

2. Create Spring REST Service using **@RestController**

Step 1: Create Java POJO class for Student

File: Student.java

```
public class Student {

    private String firstName;
    private String lastName;

    public Student() {

    }

    public Student(String firstName, String lastName) {
        this.firstName = firstName;
        this.lastName = lastName;
    }

    public String getFirstName() {
        return firstName;
    }

    public void setFirstName(String firstName) {
        this.firstName = firstName;
    }

    public String getLastName() {
        return lastName;
    }

    public void setLastName(String lastName) {
        this.lastName = lastName;
    }

}
```

Fields
Constructors
Getter/Setters

Step 2: Create @RestController

File: StudentRestController.java

```
@RestController
@RequestMapping("/api")
public class StudentRestController {

    // define endpoint for "/students" - return list of students

    @GetMapping("/students")
    public List<Student> getStudents() {

        List<Student> theStudents = new ArrayList<>();

        theStudents.add(new Student("Poornima", "Patel"));
        theStudents.add(new Student("Mario", "Rossi"));
        theStudents.add(new Student("Mary", "Smith"));

        return theStudents;
    }
}
```

We'll hard code
for now ...
can add DB later ...

Jackson will convert
List<Student> to
JSON array

Spring REST - Path Variables

Path Variables

- Retrieve a single student by id

GET

`/api/students/{studentId}` *Retrieve a single student*

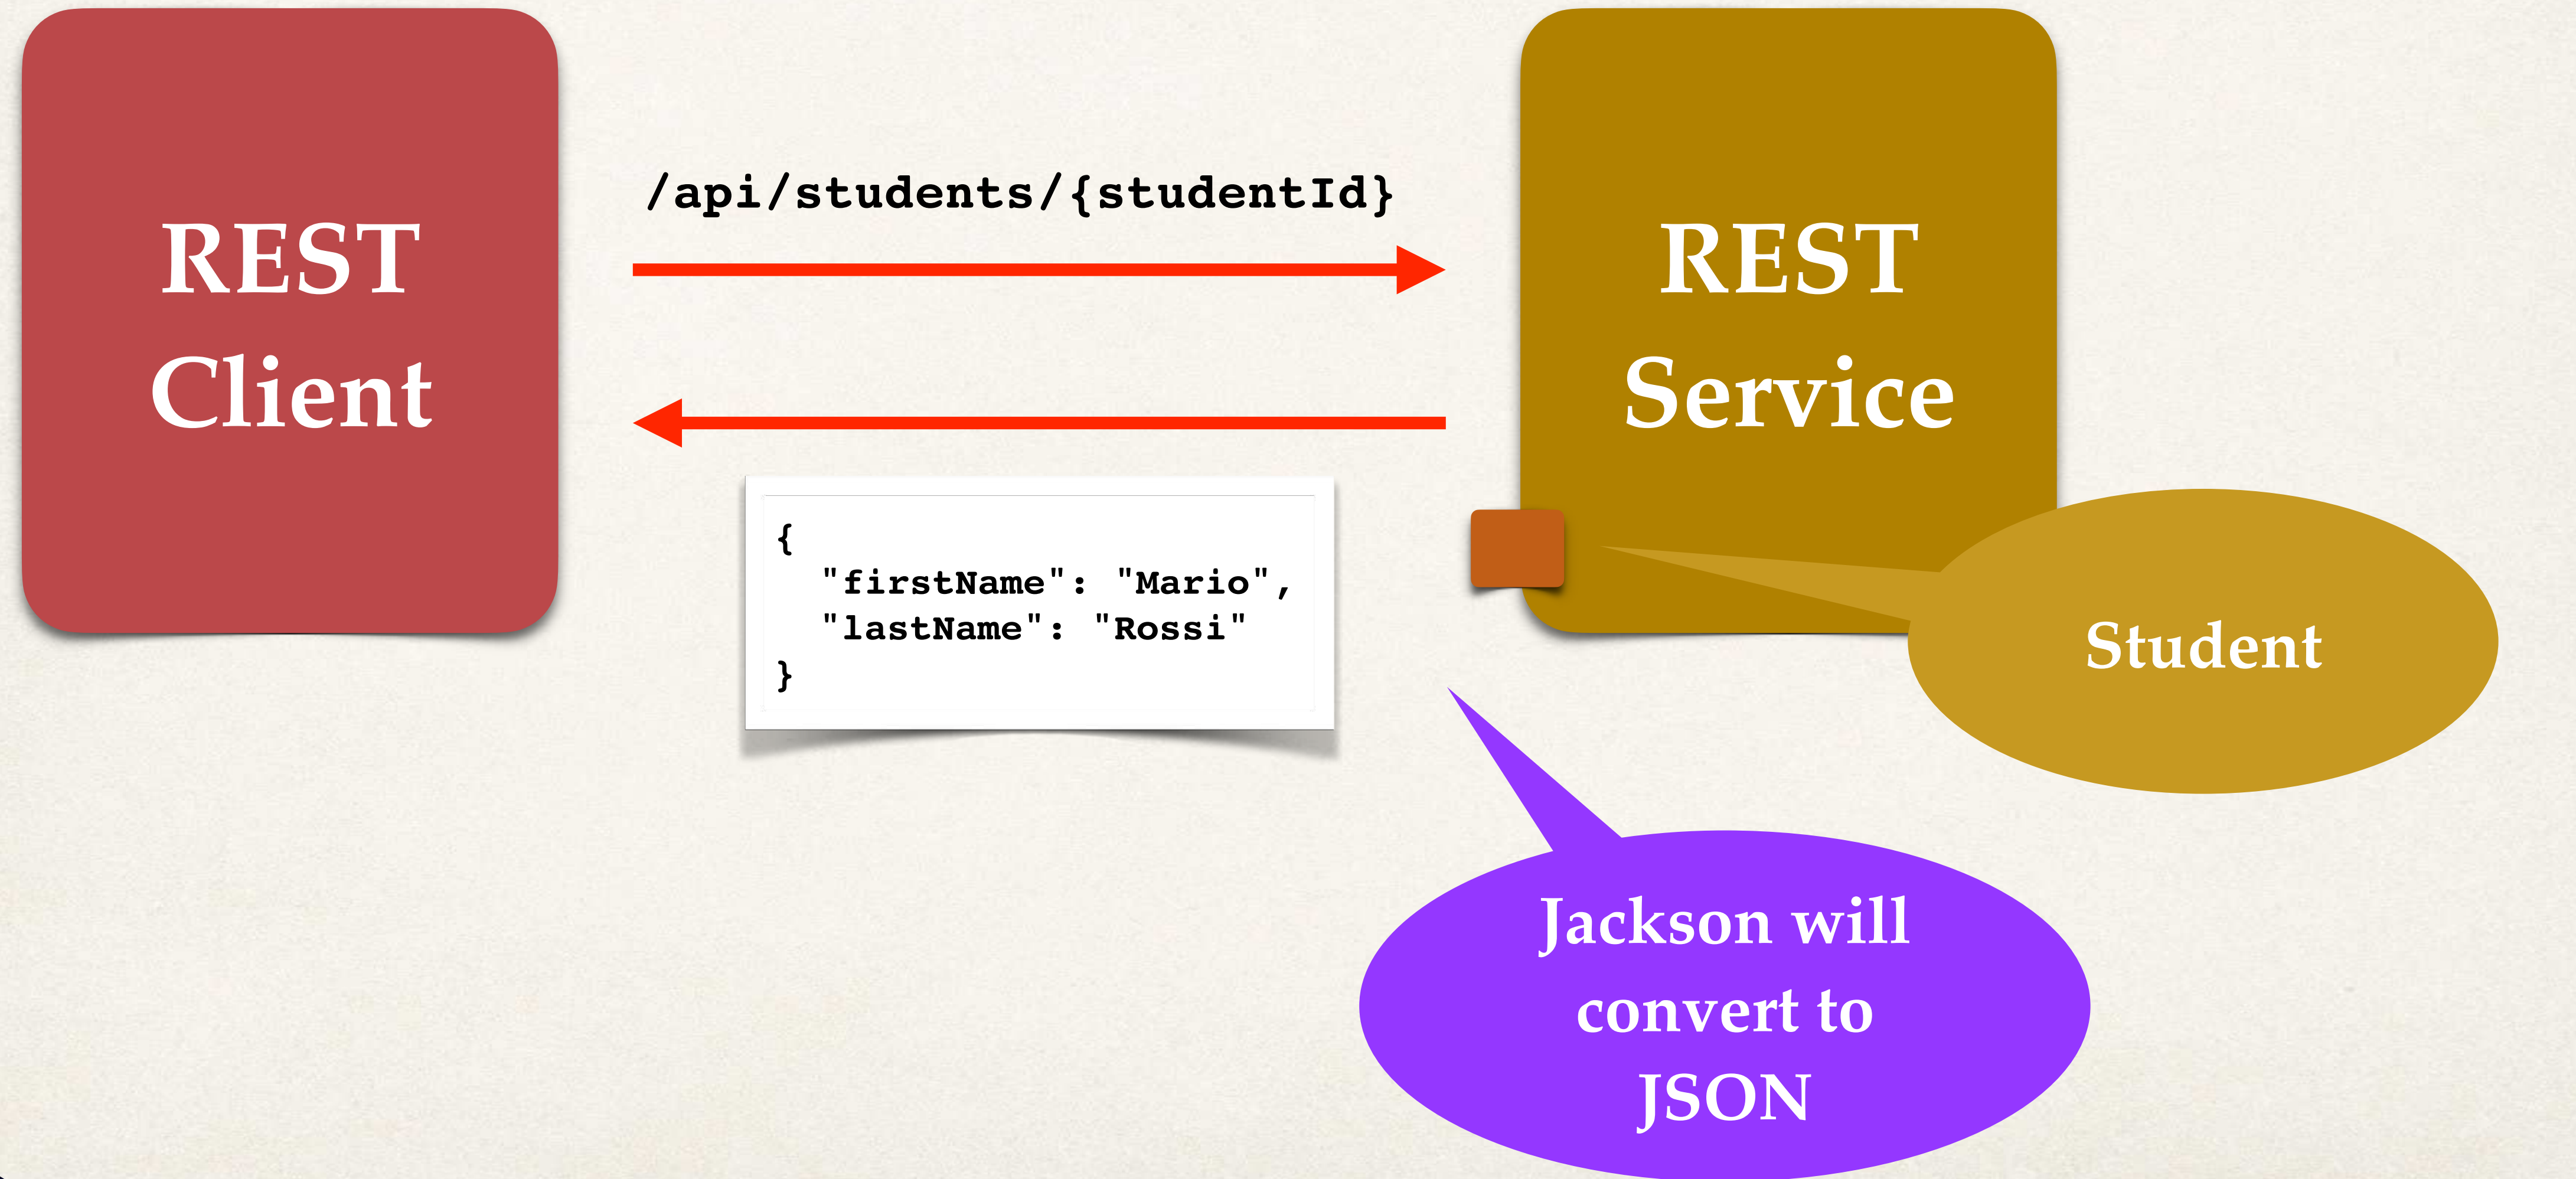

`/api/students/0`

`/api/students/1`

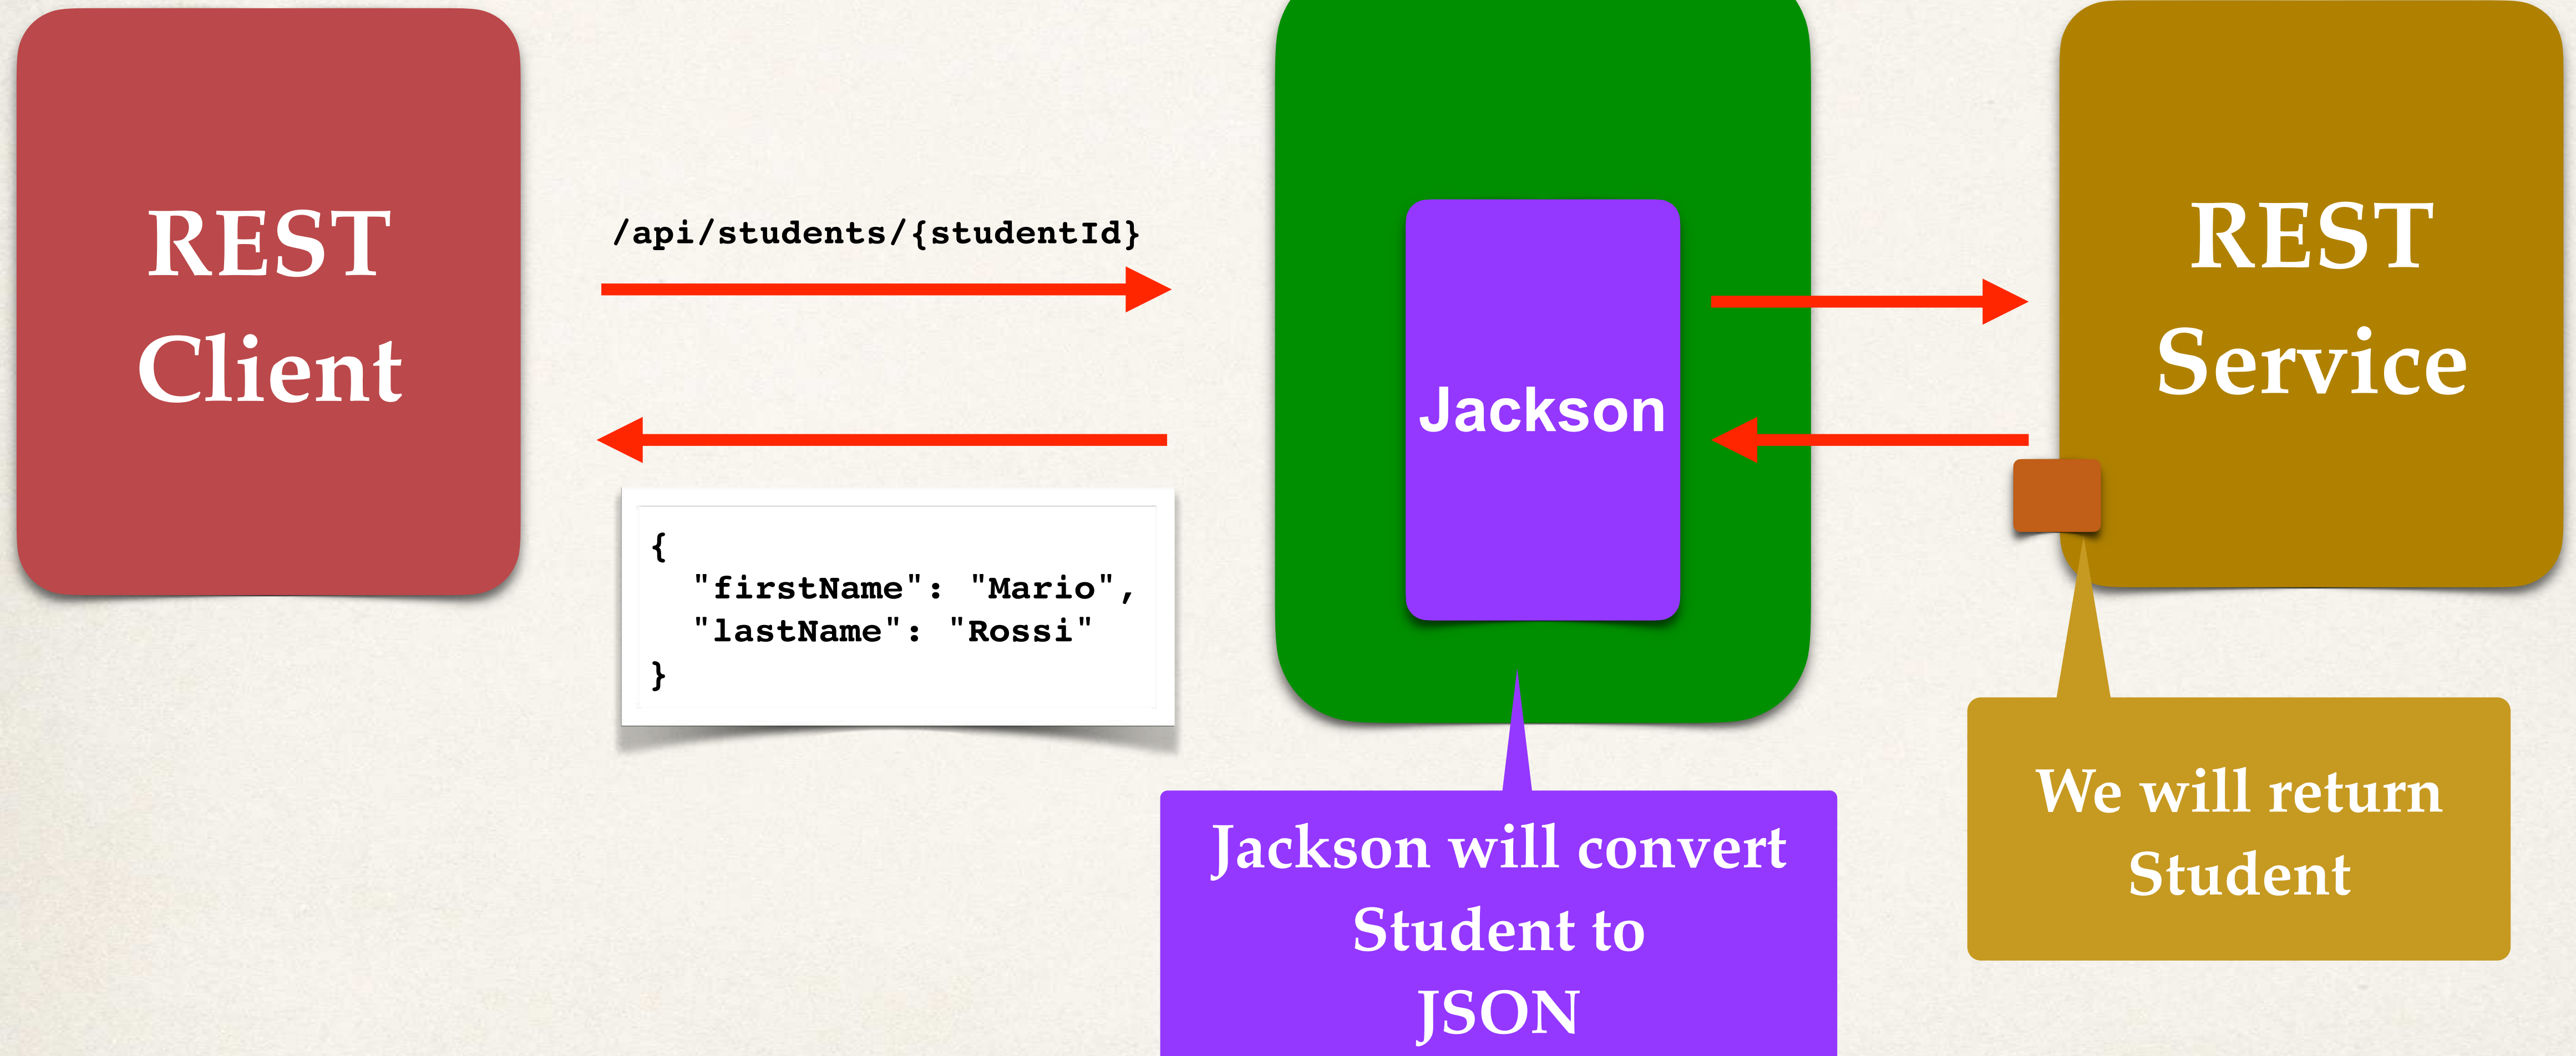

`/api/students/2`

Known as a
"path variable"

Spring REST Service

Behind the scenes

Development Process

Step-By-Step

1. Add request mapping to Spring REST Service

- Bind path variable to method parameter using `@PathVariable`

Step 1: Add Request Mapping

File: StudentRestController.java

```
@RestController
@RequestMapping("/api")
public class StudentRestController {

    // define endpoint for "/students/{studentId}" - return student at index

    @GetMapping("/students/{studentId}")
    public Student getStudent(@PathVariable int studentId) {

        List<Student> theStudents = new ArrayList<>();

        // populate theStudents
        ...

        return theStudents.get(studentId);
    }
}
```

Keep it simple,
just index into the list
We'll do fancy DB stuff later

Bind the path variable
(by default, must match)

Jackson will convert
Student to JSON

Spring REST - Exception Handling

Remember our problem?

- Bad student id of 9999 ...

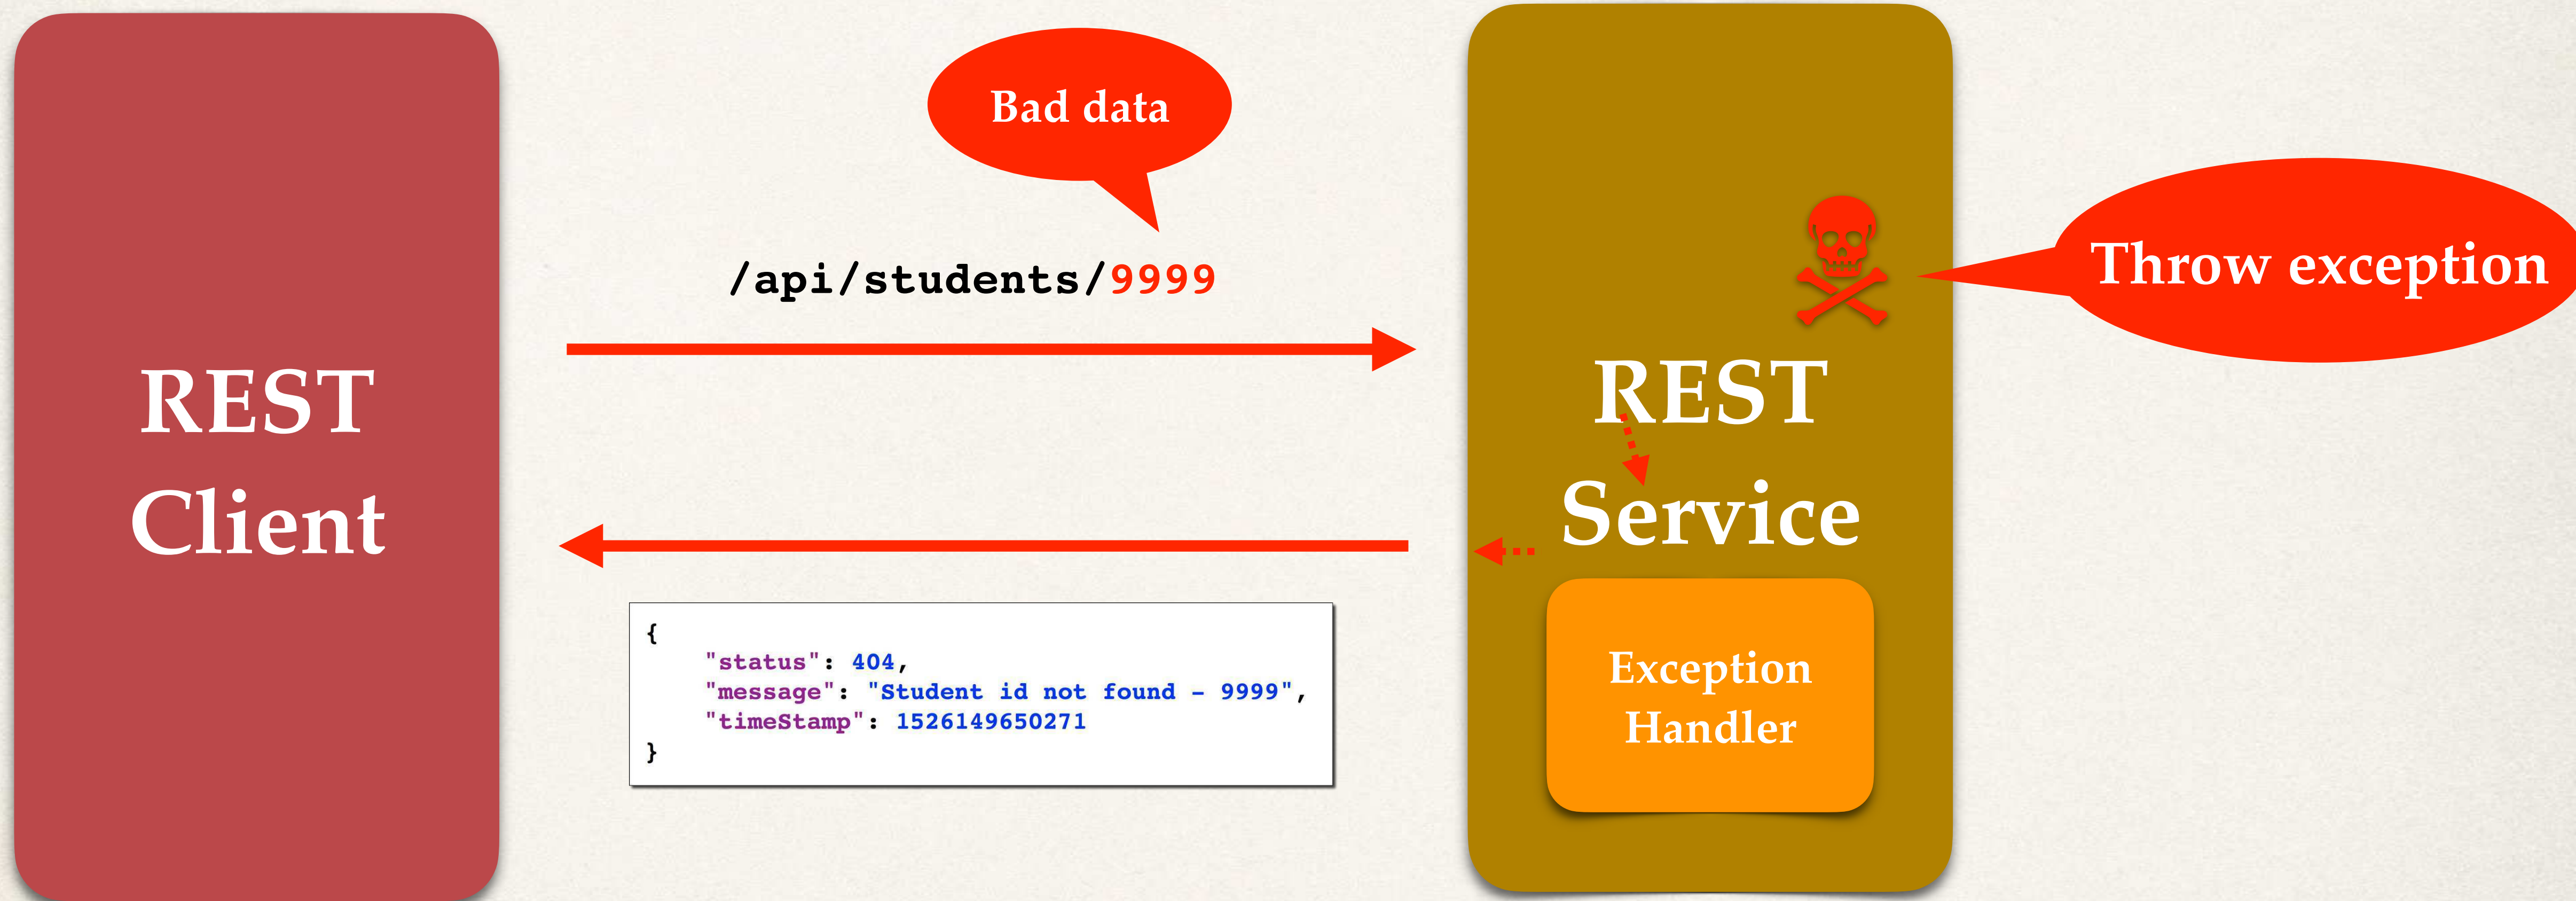

We really want this ...

- Handle the exception and return error as JSON

```
{  
  "status": 404,  
  "message": "Student id not found - 9999",  
  "timeStamp": 1526149650271  
}
```

Spring REST Exception Handling

Development Process

Step-By-Step

1. Create a custom error response class
2. Create a custom exception class
3. Update REST service to throw exception if student not found
4. Add an exception handler method using `@ExceptionHandler`

Step 1: Create custom error response class

- The custom error response class will be sent back to client as JSON

- We will define as Java class (POJO)

StudentErrorResponse
status : int message : String timeStamp : long
getStatus() : int setStatus(...) : void ...

You can define any custom fields that you want to track

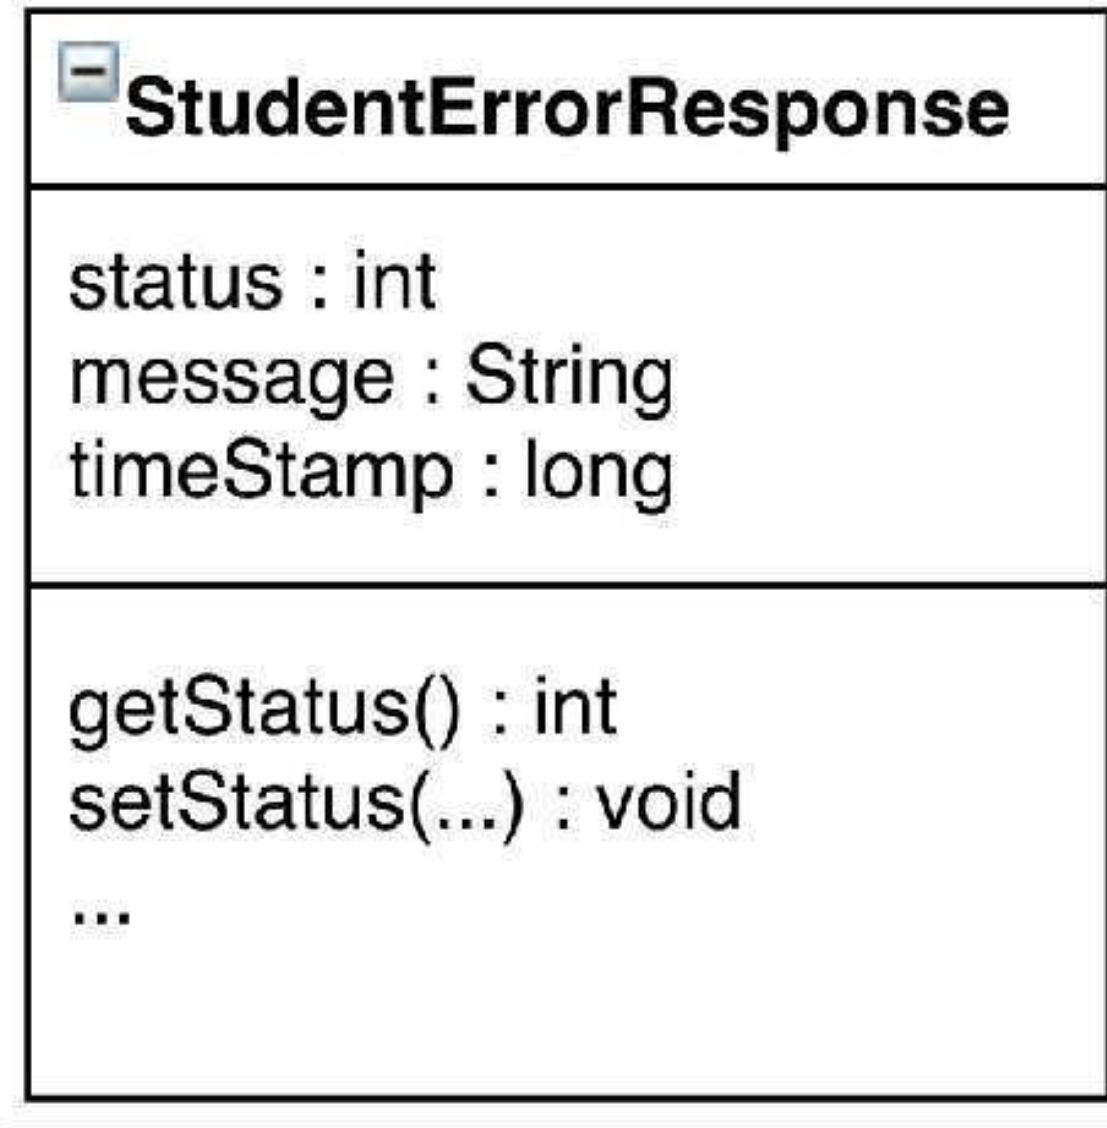

- Jackson will handle converting it to JSON

```
{  
  "status": 404,  
  "message": "Student id not found - 9999",  
  "timeStamp": 1526149650271  
}
```

Step 1: Create custom error response class

File: StudentErrorResponse.java

```
public class StudentErrorResponse {  
  
    private int status;  
    private String message;  
    private long timeStamp;  
  
    // constructors  
  
    // getters / setters  
  
}
```

```
{  
    "status": 404,  
    "message": "Student id not found - 9999",  
    "timeStamp": 1526149650271  
}
```

Step 2: Create custom student exception

- The custom student exception will be used by our REST service
- In our code, if we can't find student, then we'll throw an exception
- Need to define a custom student exception class
 - `StudentNotFoundException`

Step 2: Create custom student exception

File: StudentNotFoundException.java

```
public class StudentNotFoundException extends RuntimeException {  
  
    public StudentNotFoundException(String message) {  
        super(message);  
    }  
  
}
```

Call super class
constructor

Step 3: Update REST service to throw exception

File: StudentRestController.java

```
@RestController
@RequestMapping("/api")
public class StudentRestController {

    @GetMapping("/students/{studentId}")
    public Student getStudent(@PathVariable int studentId) {

        // check the studentId against list size

        if ( (studentId >= theStudents.size()) || (studentId < 0) ) {
            throw new StudentNotFoundException("Student id not found - " + studentId);
        }

        return theStudents.get(studentId);
    }
    ...
}
```

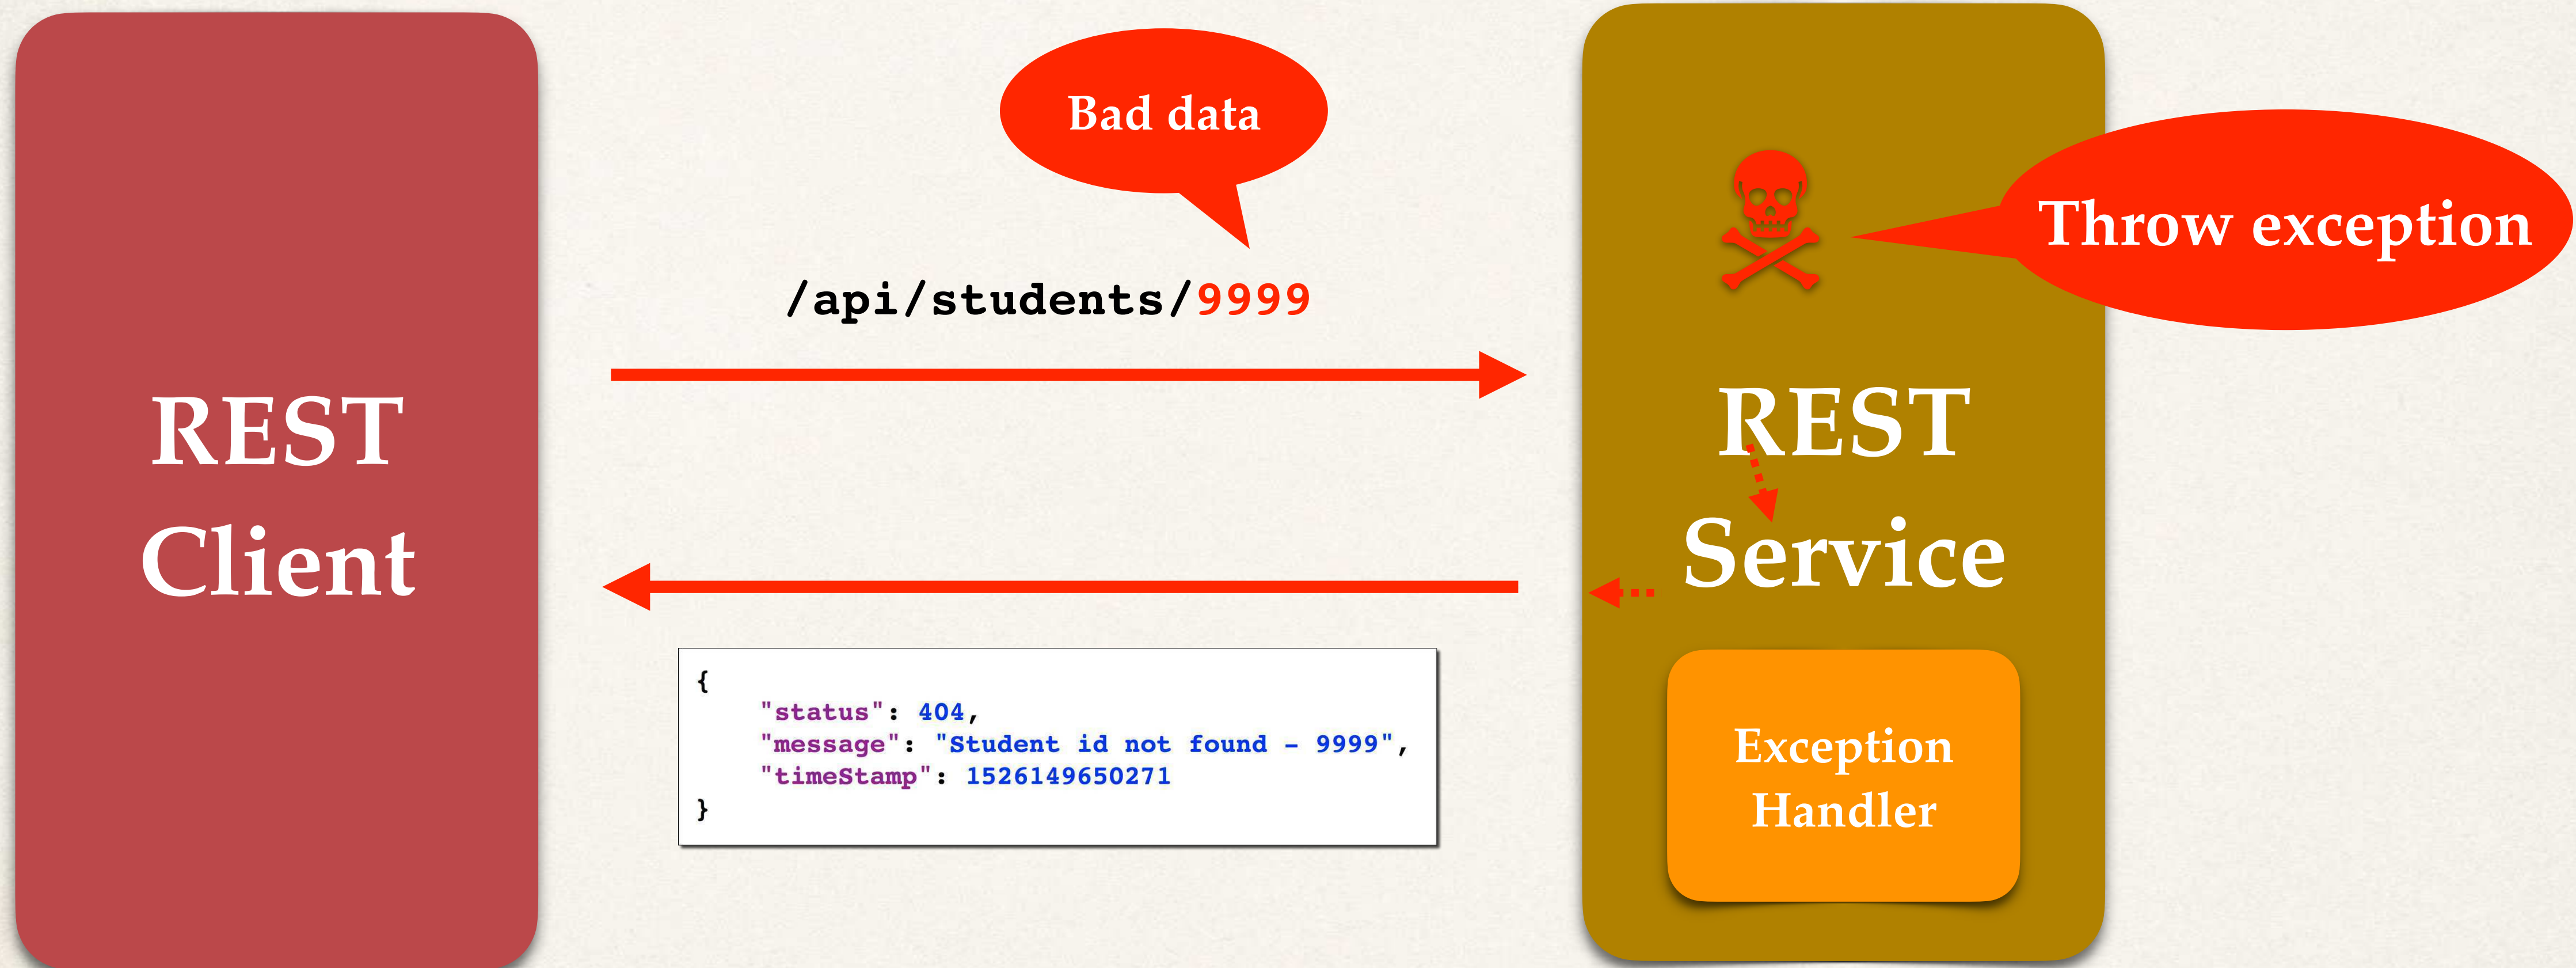

Could also
check results
from DB

Throw exception

Happy path

Spring REST Exception Handling

Step 4: Add exception handler method

- Define exception handler method(s) with `@ExceptionHandler` annotation
- Exception handler will return a `ResponseEntity`
- `ResponseEntity` is a wrapper for the HTTP response object
- `ResponseEntity` provides fine-grained control to specify:
 - HTTP status code, HTTP headers and Response body

Step 4: Add exception handler method

Exception handler method

Type of the response body

Exception type to handle / catch

```
java
@RestController(api)
public class StudentRestController {
    ...

    @ExceptionHandler
    public ResponseEntity<StudentErrorResponse> handleException(StudentNotFoundException exc) {

        StudentErrorResponse error = new StudentErrorResponse();

        error.setStatus(HttpStatus.NOT_FOUND.value());
        error.setMessage(exc.getMessage());
        error.setTimestamp(System.currentTimeMillis());

        return new ResponseEntity<>(error, HttpStatus.NOT_FOUND);
    }
}
```

Body

Status code

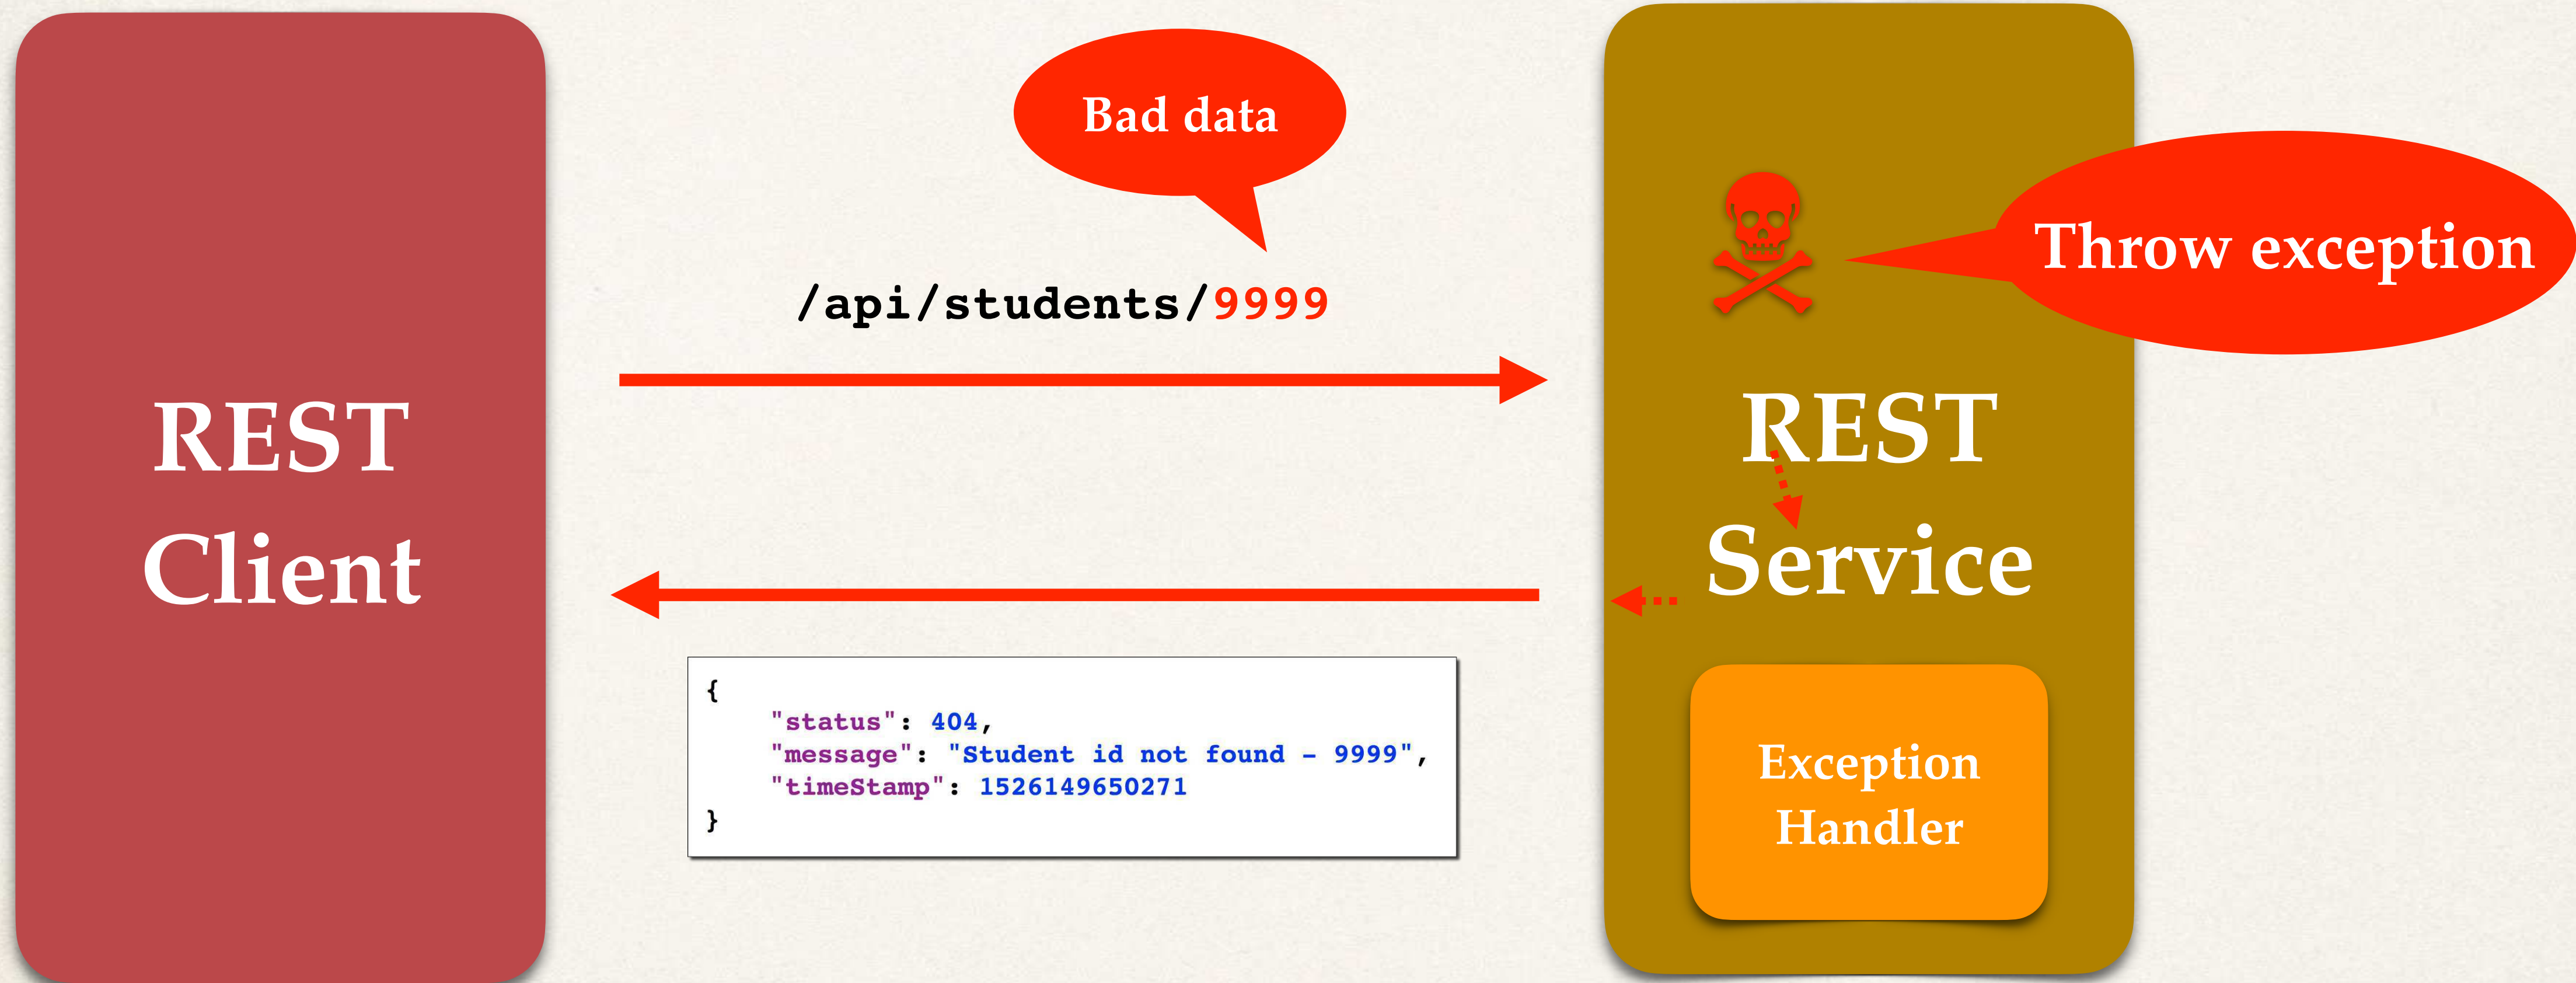

```
{
  "status": 404,
  "message": "Student id not found - 9999",
  "timestamp": 1526149650271
}
```

StudentErrorResponse

status : int
message : String
timestamp : long

getStatus() : int
setStatus(...) : void
...

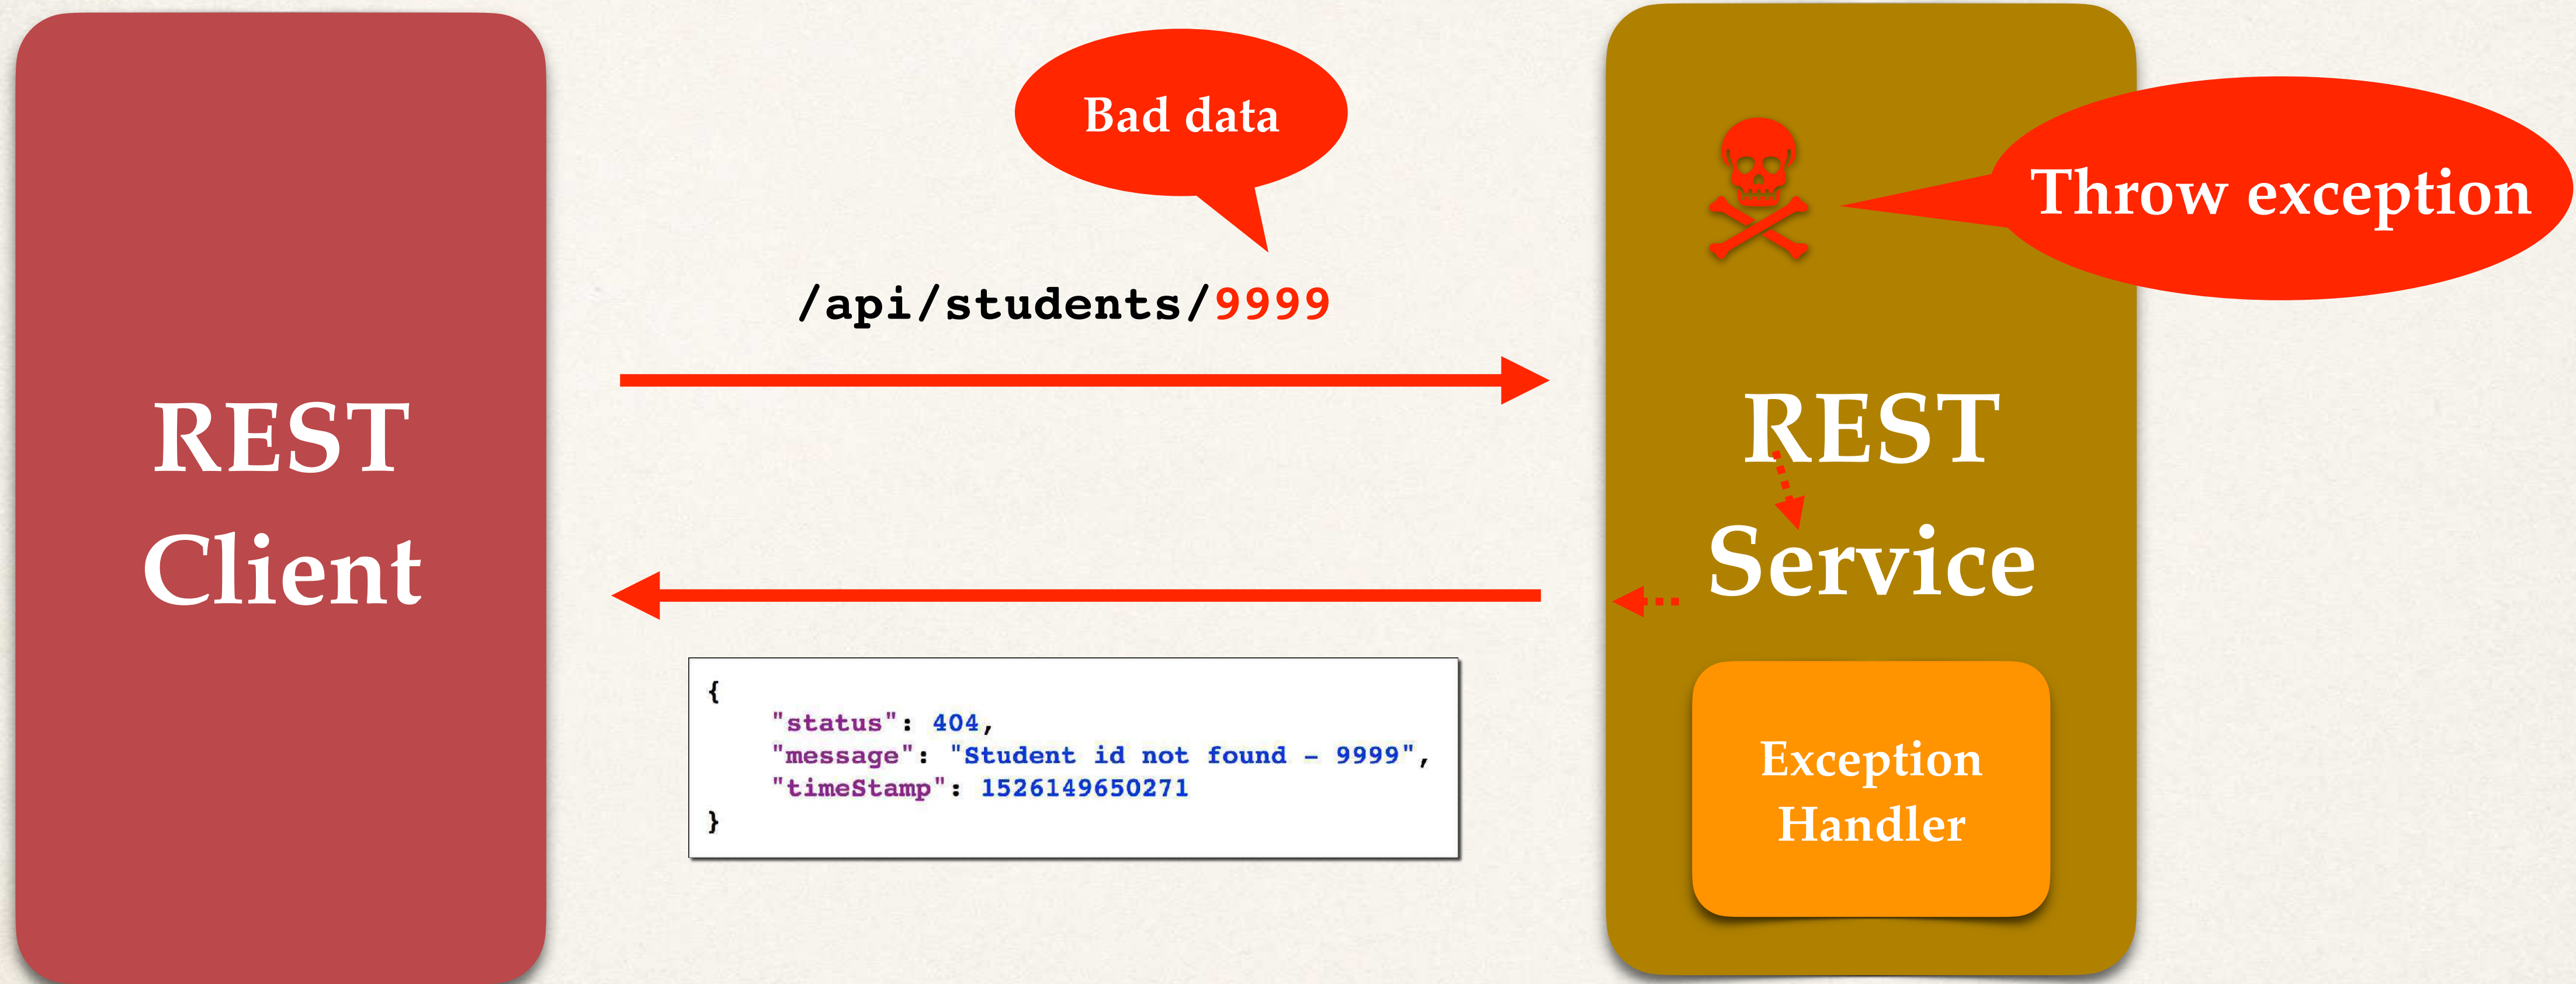

Spring REST Exception Handling

Spring REST - Global Exception Handling

Spring REST Exception Handling

It works, but ...

- Exception handler code is only for the specific REST controller
- Can't be reused by other controllers :-(
- We need **global** exception handlers
 - Promotes reuse
 - Centralizes exception handling

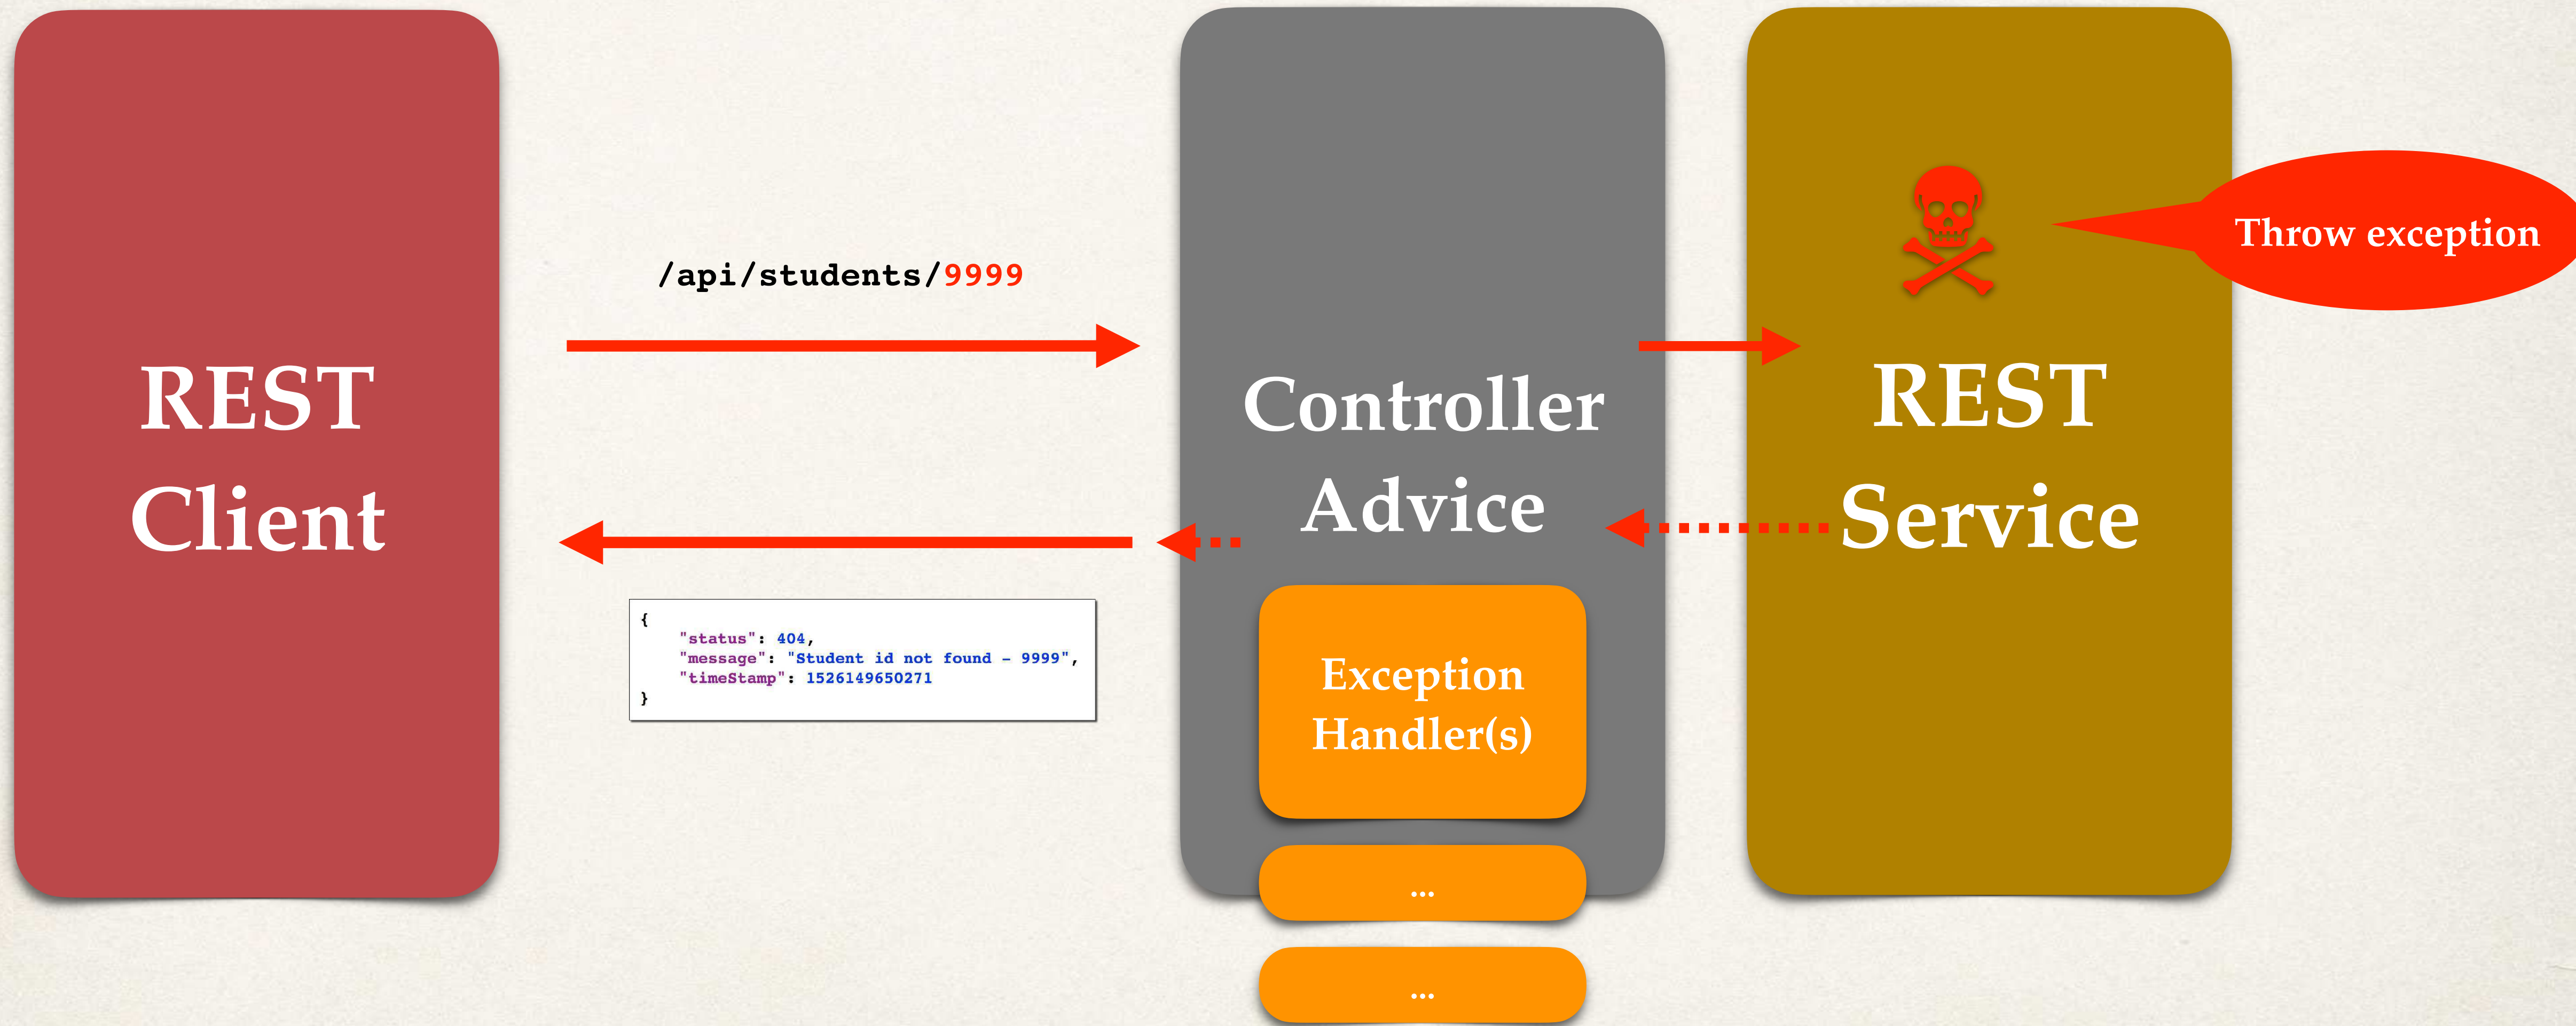

Large projects
will have
multiple controllers

Spring @ControllerAdvice

- @ControllerAdvice is similar to an interceptor / filter
- Pre-process requests to controllers
- Post-process responses to handle exceptions
- Perfect for global exception handling

**Real-time
use of
AOP**

Spring REST Exception Handling

Development Process

Step-By-Step

1. Create new `@ControllerAdvice`
2. Refactor REST service ... remove exception handling code
3. Add exception handling code to `@ControllerAdvice`

Step 1: Create new @ControllerAdvice

File: StudentRestExceptionHandler.java

```
@ControllerAdvice
public class StudentRestExceptionHandler {

    ...

}
```

Step 2: Refactor - remove exception handling

File: StudentRestController.java

```
@RestController
@RequestMapping("/api")
public class StudentRestController {
    ...

    @ExceptionHandler
    public ResponseEntity<StudentErrorResponse> handleException(StudentNotFoundException exc) {

        StudentErrorResponse error = new StudentErrorResponse();

        error.setStatus(HttpStatus.NOT_FOUND.value());
        error.setMessage(exc.getMessage());
        error.setTimeStamp(System.currentTimeMillis());

        return new ResponseEntity<>(error, HttpStatus.NOT_FOUND);
    }
}
```

Remove
this code

Step 3: Add exception handler to @ControllerAdvice

File: StudentRestExceptionHandler.java

Same code
as before

```
@ControllerAdvice
public class StudentRestExceptionHandler {

    @ExceptionHandler
    public ResponseEntity<StudentErrorResponse> handleException(StudentNotFoundException exc) {

        StudentErrorResponse error = new StudentErrorResponse();

        error.setStatus(HttpStatus.NOT_FOUND.value());
        error.setMessage(exc.getMessage());
        error.setTimestamp(System.currentTimeMillis());

        return new ResponseEntity<>(error, HttpStatus.NOT_FOUND);
    }
}
```

Spring REST Exception Handling

Spring REST API Design

REST API Design

- For real-time projects, who will use your API?
- Also, how will they use your API?
- Design the API based on requirements

API Design Process

Step-By-Step

1. Review API requirements
2. Identify main resource / entity
3. Use HTTP methods to assign action on resource

API Requirements

From the Boss

Create a REST API for the Employee Directory

REST clients should be able to

- Get a list of employees
- Get a single employee by id
- Add a new employee
- Update an employee
- Delete an employee

Step 2: Identify main resource / entity

- To identify main resource / entity, look for the most prominent "noun"
- For our project, it is "employee"
- Convention is to use plural form of resource / entity: **employees**

`/api/employees`

Step 3: Use HTTP methods to assign action on resource

HTTP Method	CRUD Action
POST	<u>C</u> reate a new entity
GET	<u>R</u> ead a list of entities or single entity
PUT	<u>U</u> pdate an existing entity
DELETE	<u>D</u> eleate an existing entity

Full
CRUD

Employee Real-Time Project

HTTP Method	Endpoint	CRUD Action
POST	/api/employees	<u>C</u> reate a new employee
GET	/api/employees	<u>R</u> ead a list of employees
GET	/api/employees/{employeeId}	<u>R</u> ead a single employee
PUT	/api/employees	<u>U</u> pdate an existing employee
DELETE	/api/employees/{employeeId}	<u>D</u> elete an existing employee

Anti-Patterns

- DO NOT DO THIS ... these are REST anti-patterns, bad practice

`/api/employeesList`
`/api/deleteEmployee`
`/api/addEmployee`
`/api/updateEmployee`

Don't include actions in the endpoint

Instead, use
HTTP methods
to assign actions

Employee Real-Time Project

HTTP Method	Endpoint	CRUD Action
POST	/api/employees	<u>C</u> reate a new employee
GET	/api/employees	<u>R</u> ead a list of employees
GET	/api/employees/{employeeId}	<u>R</u> ead a single employee
PUT	/api/employees	<u>U</u> pdate an existing employee
DELETE	/api/employees/{employeeId}	<u>D</u> eleate an existing employee

More API Examples

- On the following slides, we'll look at APIs from other real-time projects
- PayPal
- GitHub
- Salesforce

PayPal

- PayPal Invoicing API
 - <https://developer.paypal.com/docs/api/invoicing/>

PayPal Developer Docs APIs Support

Create draft invoice

POST /v1/invoicing/invoices

List invoices

GET /v1/invoicing/invoices

Show invoice details

GET /v1/invoicing/invoices/{invoice_id}

Update invoice

PUT /v1/invoicing/invoices/{invoice_id}

Delete draft invoice

DELETE /v1/invoicing/invoices/{invoice_id}

GitHub

- GitHub Repositories API
 - `https://developer.github.com/v3/repos/#repositories`

GitHub Developer

Create a new repository

POST /user/repos

Delete a repository

DELETE /repos/:owner/:repo

List your repositories

GET /user/repos

Get a repository

GET /repos/:owner/:repo

SalesForce REST API

- Industries REST API
- <https://sforce.co/2J40ALH>

Retrieve All Individuals

GET /services/apexrest/v1/individual/

Retrieve One Individual

GET /services/apexrest/v1/individual/{individual_id}

Create an individual

POST /services/apexrest/clinic01/v1/individual/

Update an individual

PUT /services/apexrest/clinic01/v1/individual/

Spring Boot REST API - Real Time Project

Real-Time Project

REST API with Spring Boot that connects to a database

API Requirements

From the Boss

Create a REST API for the Employee Directory

REST clients should be able to

- Get a list of employees
- Get a single employee by id
- Add a new employee
- Update an employee
- Delete an employee

Development Process

Step-By-Step

1. Set up Database Dev Environment
2. Create Spring Boot project using Spring Initializr
3. Get list of employees
4. Get single employee by ID
5. Add a new employee
6. Update an existing employee
7. Delete an existing employee

Application Architecture

Setup Database Table

employee.sql

1. File: employee.sql
2. Create a new database table: **employee**
3. Load table with sample data

Details on downloading the SQL file
provided in next section

Creating Spring Boot Project

Development Process

Step-By-Step

1. Set up Database Dev Environment
2. Create Spring Boot project using Spring Initializr
3. Get list of employees
4. Get single employee by ID
5. Add a new employee
6. Update an existing employee
7. Delete an existing employee

Our Task

Create DAO in Spring Boot

Application Architecture

Development Process

1. Set up Database Dev Environment
2. Create Spring Boot project using Spring Initializr

3. Get list of employees
4. Get single employee by ID
5. Add a new employee
6. Update an existing employee
7. Delete an existing employee

Step-By-Step

**Let's build a
DAO layer for this**

DAO Interface

```
public interface EmployeeDAO {  
  
    List<Employee> findAll();  
  
}
```

DAO Impl

Same interface for
consistent API

```
@Repository
public class EmployeeDAOJpaImpl implements EmployeeDAO {

    private EntityManager entityManager;

    @Autowired
    public EmployeeDAOJpaImpl(EntityManager theEntityManager) {
        entityManager = theEntityManager;
    }

    ...
}
```

Automatically created
by Spring Boot

Constructor
injection

Get a list of employees

```
@Override
public List<Employee> findAll() {

    // create a query
    TypedQuery<Employee> theQuery =
        entityManager.createQuery("from Employee", Employee.class);

    // execute query and get result list
    List<Employee> employees = theQuery.getResultList();

    // return the results
    return employees;
}
```

Development Process

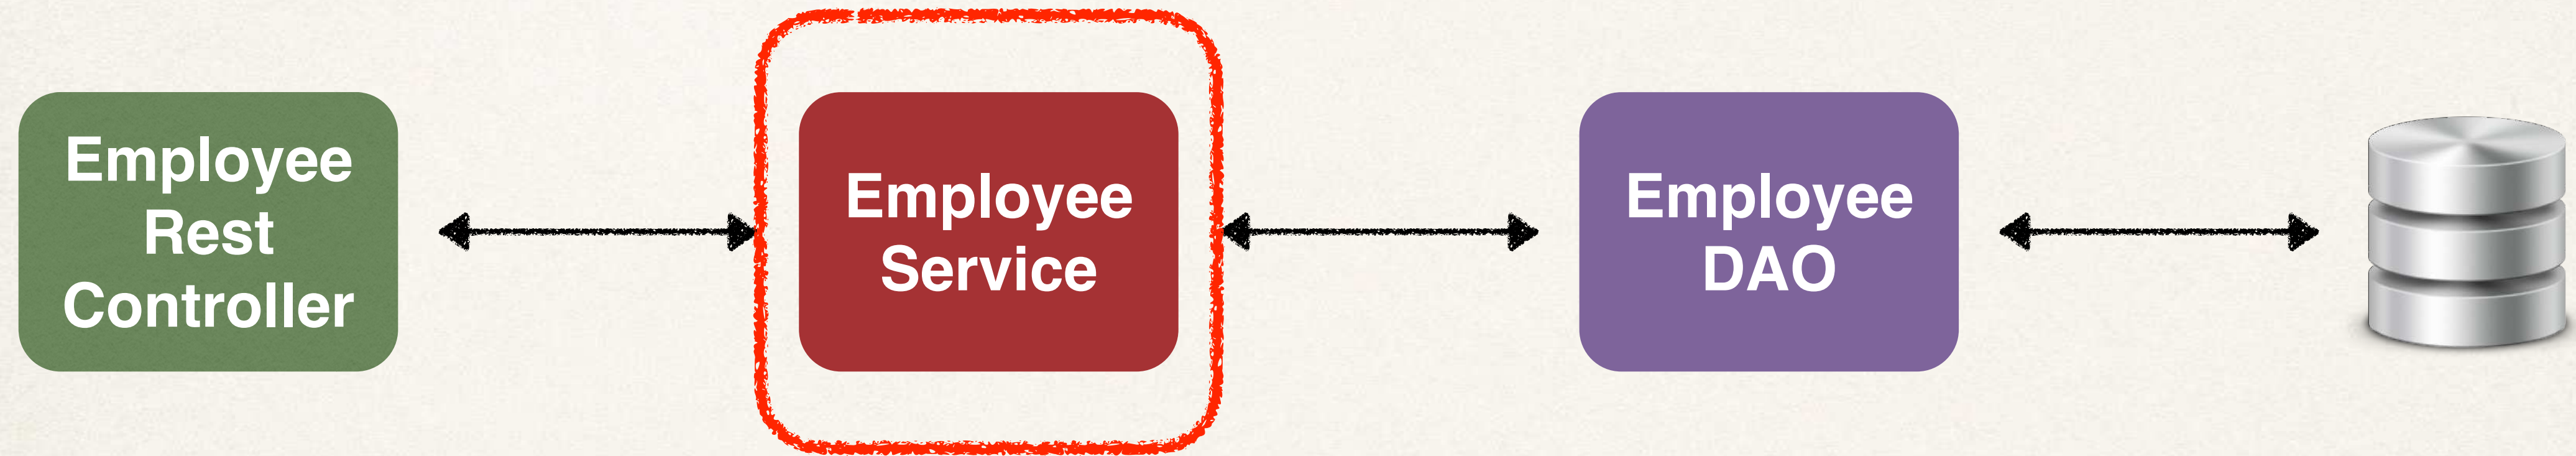

Step-By-Step

1. Update db configs in application.properties
2. Create Employee entity
3. Create DAO interface
4. Create DAO implementation
5. Create REST controller to use DAO

Define Services with @Service

Refactor: Add a Service Layer

Purpose of Service Layer

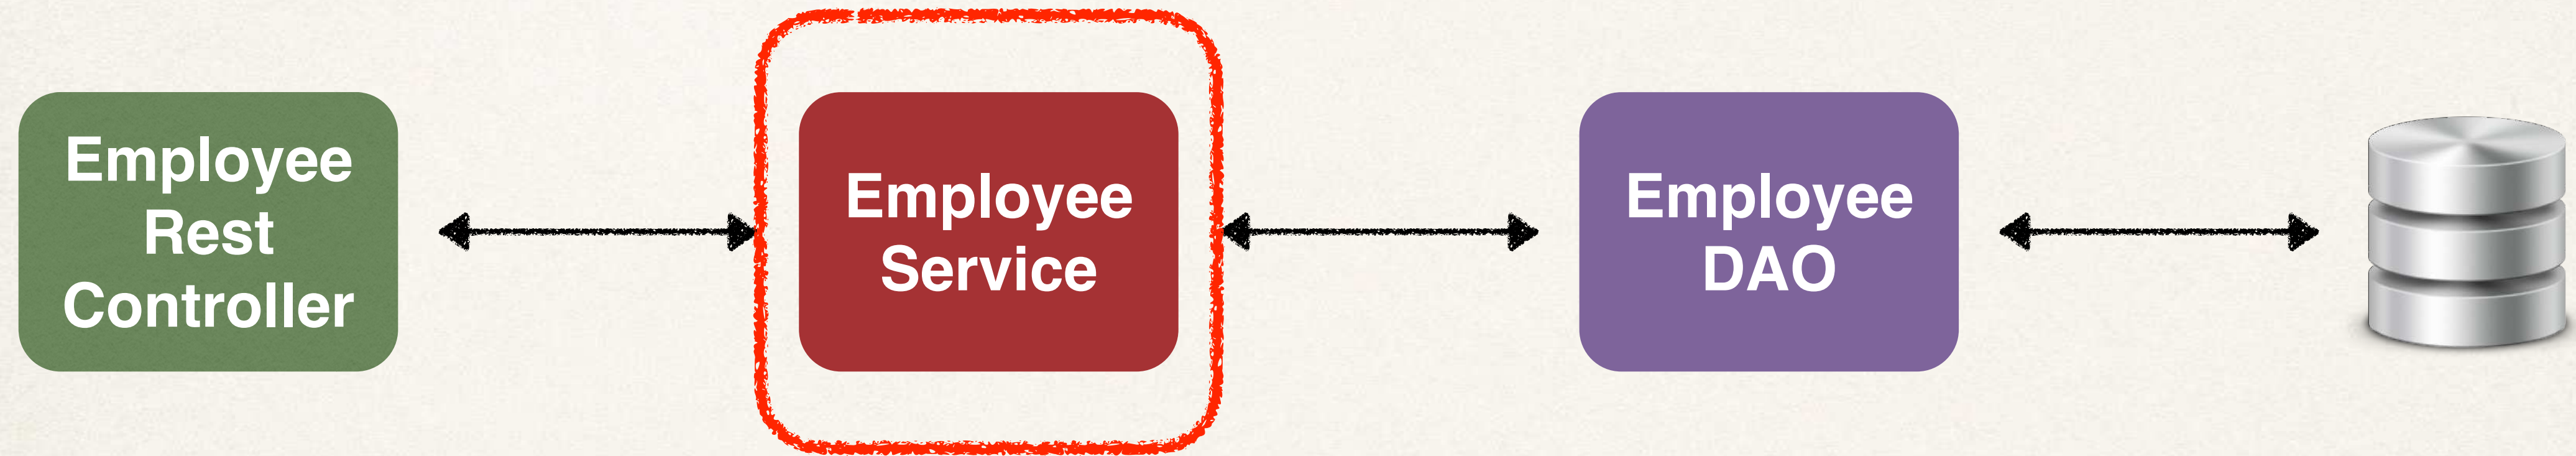

- ❖ Service Facade design pattern
- ❖ Intermediate layer for custom business logic
- ❖ Integrate data from multiple sources (DAO/repositories)

Integrate Multiple Data Sources

Most Times - Delegate Calls

Specialized Annotation for Services

- Spring provides the **@Service** annotation

Specialized Annotation for Services

- **@Service** applied to Service implementations
- Spring will automatically register the Service implementation
 - thanks to component-scanning

Employee Service

1. Define Service interface
2. Define Service implementation
 - Inject the EmployeeDAO

Step-By-Step

Step 1: Define Service interface

```
public interface EmployeeService {  
  
    List<Employee> findAll();  
  
}
```

Step 2: Define Service implementation

@Service - enables component scanning

@Service

public class EmployeeServiceImpl **implements** EmployeeService {

// inject EmployeeDAO ...

@Override

public List<Employee> findAll() {
 return employeeDAO.findAll();

}

}

DAO: Find, Add, Update and Delete

Service Layer - Best Practice

- ❖ Best practice is to apply transactional boundaries at the service layer
- ❖ It is the service layer's responsibility to manage transaction boundaries
- ❖ For implementation code
 - ❖ Apply @Transactional on service methods
 - ❖ Remove @Transactional on DAO methods if they already exist

Development Process

Step-By-Step

1. Set up Database Dev Environment
2. Create Spring Boot project using Spring Initializr
3. Get list of employees
4. Get single employee by ID
5. Add a new employee
6. Update an existing employee
7. Delete an existing employee

DAO methods

DAO: Get a single employee

```
@Override
public Employee findById(int theId) {

    // get employee
    Employee theEmployee = entityManager.find(Employee.class, theId);

    // return employee
    return theEmployee;
}
```

DAO: Add or Update employee

Note: We don't use @Transactional at DAO layer
It will be handled at Service layer

```
@Override
public Employee save(Employee theEmployee) {

    // save or update the employee
    Employee dbEmployee = entityManager.merge(theEmployee);

    // return dbEmployee
    return dbEmployee;
}
```

if id == 0
then save/insert
else update

Return dbEmployee
It has updated id from the database
(in the case of insert)

DAO: Delete an existing employee

Note: We don't use @Transactional at DAO layer
It will be handled at Service layer

```
@Override
public void deleteById(int theId) {

    // find the employee by id
    Employee theEmployee = entityManager.find(Employee.class, theId);

    // delete the employee
    entityManager.remove(theEmployee);
}
```

DAO: Find, Add, Update and Delete

Development Process

Step-By-Step

1. Set up Database Dev Environment
2. Create Spring Boot project using Spring Initializr
3. Get list of employees
4. Get single employee by ID
5. Add a new employee
6. Update an existing employee
7. Delete an existing employee

DAO methods

Service: Find, Add, Update and Delete

Development Process

Step-By-Step

1. Set up Database Dev Environment
2. Create Spring Boot project using Spring Initializr
3. Get list of employees
4. Get single employee by ID
5. Add a new employee
6. Update an existing employee
7. Delete an existing employee

Service methods

Rest Controller Methods - Find and Add

Development Process

Step-By-Step

1. Set up Database Dev Environment
2. Create Spring Boot project using Spring Initializr
3. Get list of employees
4. Get single employee by ID
5. Add a new employee
6. Update an existing employee
7. Delete an existing employee

Rest Controller
methods

Read a Single Employee

REST
Client

GET

/api/employees/{employeeId}

Employee
REST
Controller

```
{  
  "id": 1,  
  "firstName": "David",  
  "lastName": "Adams",  
  "email": "david@luv2code.com"  
}
```

Create a New Employee

Since new employee,
we are not
passing id / primary key

REST
Client

POST

/api/employees

```
{  
  "firstName": "Juan",  
  "lastName": "Perez",  
  "email": "juan.perez@luv2code.com"  
}
```

Employee
REST
Controller

Response contains
new id / primary key

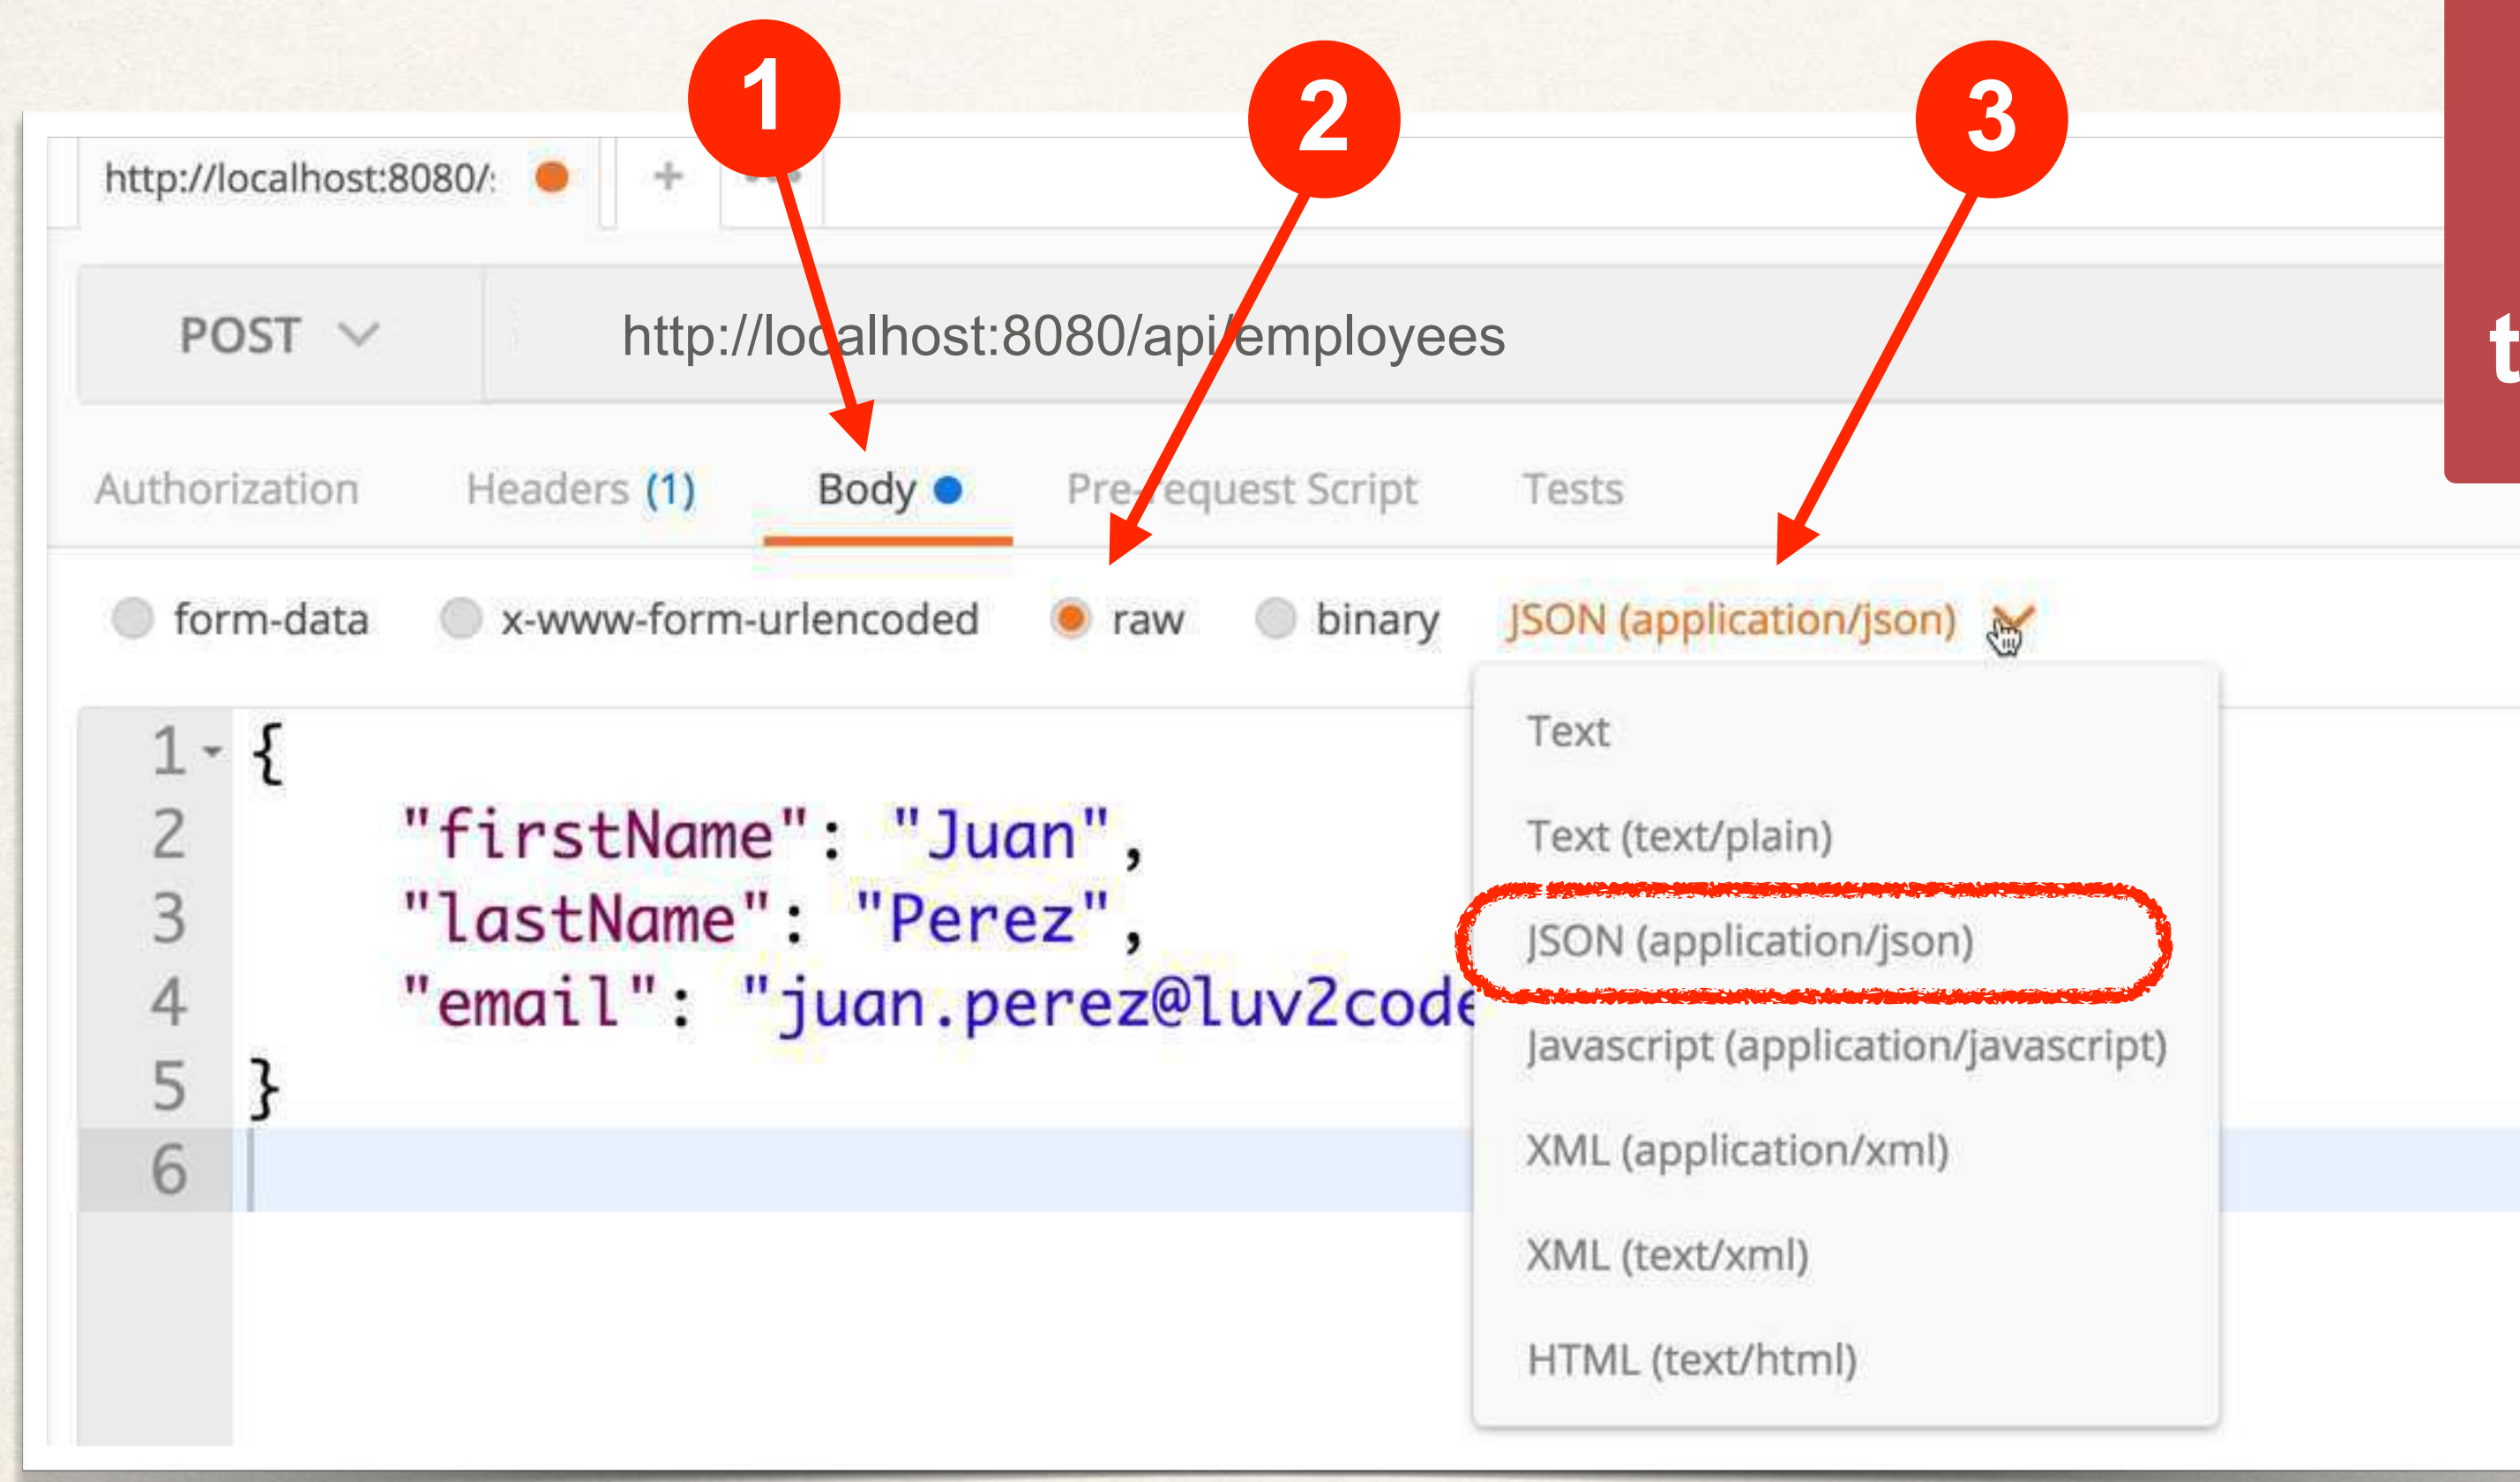

```
{  
  "id": 7,  
  "firstName": "Juan",  
  "lastName": "Perez",  
  "email": "juan.perez@luv2code.com"  
}
```

Sending JSON to Spring REST Controllers

- When sending JSON data to Spring REST Controllers
- For controller to process JSON data, need to set a HTTP request header
 - `Content-type: application/json`
- Need to configure REST client to send the correct HTTP request header

Postman - Sending JSON in Request Body

- Must set HTTP request header in Postman

Based on these configs, Postman will automatically set the correct HTTP request header

Rest Controller Methods - Update and Delete

Development Process

Step-By-Step

1. Set up Database Dev Environment
2. Create Spring Boot project using Spring Initializr
3. Get list of employees
4. Get single employee by ID
5. Add a new employee
6. Update an existing employee
7. Delete an existing employee

Rest Controller methods

Update Employee

ID of employee to update
With updated info

PUT

/api/employees

```
{  
  "id" : 1,  
  "firstName" : "Daniel",  
  "lastName" : "Vega",  
  "email" : "daniel.vega@luv2code.com"  
}
```

REST
Client

Employee
REST
Controller

```
{  
  "id" : 1,  
  "firstName" : "Daniel",  
  "lastName" : "Vega",  
  "email" : "daniel.vega@luv2code.com"  
}
```

Response contains
updated info (echoed)

Delete Employee

Rest Controller Methods

Partial Updates - Patch

Common Pitfall - Partial Update Employee

id	first_name	last_name	email
5	Juan	Vega	juan@luv2code.com

Partial update ...
only the email address

REST
Client

PUT

/api/employees

```
{  
  "id": 5,  
  "email": "vega.juan@demo.com"  
}
```

Employee
REST
Controller

```
{  
  "id": 5,  
  "firstName": null,  
  "lastName": null,  
  "email": "vega.juan@demo.com"  
}
```

Notice how the other
fields are null :-)

Partial Updates - Patch

- For partial updates, need to use **HTTP PATCH**
- Comparison
 - PUT: Replaces the entire resource
 - PATCH: Modifies only specified parts of resource (partial)
- Benefits of **PATCH**
 - Efficiency: Reducing bandwidth by sending only partial changes
 - Flexibility: Allows multiple partial updates in a single request

PATCH - Partial Update Employee

id	first_name	last_name	email
5	Juan	Vega	juan@luv2code.com

Partial update ...
only the email address

PATCH `/api/employees/5`

REST API convention
is to pass the id
as a path variable

REST
Client

```
{  
  "email": "vega.juan@demo.com"  
}
```

Employee
REST
Controller

```
{  
  "id": 5,  
  "firstName": "Juan",  
  "lastName": "Vega",  
  "email": "vega.juan@demo.com"  
}
```

Notice how partial updates
are applied correctly

PATCH - Partial Update on multiple fields

id	first_name	last_name	email
5	Juan	Vega	juan@luv2code.com

Partial update ...
on multiple fields

PATCH `/api/employees/5`

```
{  
  "firstName": "Daniel",  
  "email": "vega@demo.com"  
}
```

REST
Client

Employee
REST
Controller

```
{  
  "id": 5,  
  "firstName": "Daniel", ✓  
  "lastName": "Vega",  
  "email": "vega@demo.com" ✓  
}
```

Notice how partial updates
are applied correctly

PATCH - Development Process

Step-By-Step

1. Inject helper class: ObjectMapper
2. Add support for @PatchMapping request method
3. Apply patch payload to employee

Step 1: Inject helper class: ObjectMapper

- ObjectMapper is a helper class in the Jackson library for JSON processing
- ObjectMapper provides following support
 - Converts Java objects to JSON and vice-versa
 - Allows merging of JSON nodes
 - Provides type safety for conversions: Java $\leftrightarrow$ JSON
- The ObjectMapper is preconfigured by Spring Boot

Step 1: Inject helper class: ObjectMapper

```
import com.fasterxml.jackson.databind.ObjectMapper;
```

Helper class from Jackson library

```
@RestController
```

```
@RequestMapping("/api")
```

```
public class EmployeeRestController {
```

```
    private ObjectMapper objectMapper;
```

```
    @Autowired
```

```
    public EmployeeRestController(EmployeeService theEmployeeService, ObjectMapper theObjectMapper) {
```

```
        employeeService = theEmployeeService;
```

```
        objectMapper = theObjectMapper;
```

```
    }
```

```
    ...
```

```
}
```

ObjectMapper is
auto-configured by Spring Boot
for JSON processing

Step 2: Add support for @PatchMapping request method

```
@PatchMapping("/employees/{employeeId}")
public Employee patchEmployee(@PathVariable int employeeId, @RequestBody Map<String, Object> patchPayload) {

    Employee tempEmployee = employeeService.findById(employeeId);

    // throw exception if null
    if (tempEmployee == null) {
        throw new RuntimeException("Employee id not found - " + employeeId);
    }

    // throw exception if request body updates contains id
    if (patchPayload.containsKey("id")) {
        throw new RuntimeException("Employee id not allowed in request body - " + employeeId);
    }

    Employee patchedEmployee = apply(patchPayload, tempEmployee);

    Employee dbEmployee = employeeService.save(patchedEmployee);

    return dbEmployee;
}
```

The "id" field is not allowed in the payload
We will not change primary key

Apply the partial patch updates
Method defined in next step ...

Step 3: Apply patch payload to employee

```
private Employee apply(Map<String, Object> patchPayload, Employee tempEmployee) {  
  
    // Convert employee object to a JSON object node  
    ObjectNode employeeNode = objectMapper.convertValue(tempEmployee, ObjectNode.class);  
  
    // Convert the patchPayload map to a JSON object node  
    ObjectNode patchNode = objectMapper.convertValue(patchPayload, ObjectNode.class);  
  
    // Merge the patch updates into the employee node  
    employeeNode.setAll(patchNode);  
  
    return objectMapper.convertValue(employeeNode, Employee.class);  
}
```

Convert JSON object node
back to Employee object

PATCH - Partial Update Employee

id	first_name	last_name	email
5	Juan	Vega	juan@luv2code.com

Partial update ...
only the email address

PATCH /api/employees/5

```
{  
  "email": "vega.juan@demo.com"  
}
```

REST
Client

Employee
REST
Controller

```
{  
  "id": 5,  
  "firstName": "Juan",  
  "lastName": "Vega",  
  "email": "vega.juan@demo.com"  
}
```

Notice how partial updates
are applied correctly

PATCH

- The approach shown in the previous slides covers the majority of use cases for partial updates
- However, if you have complex use cases
 - Deeply nested JSON entities
 - Add, move, remove, copy fields
 - Move / manipulate array elements
 - Complex transformations / data enrichment
- RFC 6902 - JSON Patch - <https://www.rfc-editor.org/rfc/rfc6902.html>
- RFC 7386 - JSON Merge Patch - <https://www.rfc-editor.org/rfc/rfc7386.html>
- json-patch project - <https://github.com/java-json-tools/json-patch>

Spring Data JPA in Spring Boot

Application Architecture

The Problem

- We saw how to create a DAO for **Employee**
- What if we need to create a DAO for another entity?
- **Customer, Student, Product, Book ...**
- Do we have to repeat all of the same code again???

```
public interface EmployeeDAO {  
  
    public List<Employee> findAll();  
  
    public Employee findById(int theId);  
  
    public void save(Employee theEmployee);  
  
    public void deleteById(int theId);  
  
}
```

```
@Repository  
public class EmployeeDAOJpaImpl implements EmployeeDAO {  
  
    private EntityManager entityManager;  
  
    @Autowired  
    public EmployeeDAOJpaImpl(EntityManager theEntityManager) {  
        entityManager = theEntityManager;  
    }  
  
    @Override  
    public List<Employee> findAll() {  
  
        // create a query  
        TypedQuery<Employee> theQuery =  
            entityManager.createQuery("from Employee", Employee.class);  
  
        // execute query and get result list  
        List<Employee> employees = theQuery.getResultList();  
  
        // return the results  
        return employees;  
    }  
  
    @Override  
    public Employee findById(int theId) {  
  
        // get employee  
        Employee theEmployee =  
            entityManager.find(Employee.class, theId);  
  
        // return employee  
        return theEmployee;  
    }  
}
```

Creating DAO

- You may have noticed a pattern with creating DAOs

```
@Override
public Employee findById(int theId) {

    // get data
    Employee theData = entityManager.find(Employee.class, theId);

    // return data
    return theData;
}
```

Most of the code
is the same

Only difference is the
entity type and primary key

Entity type

Primary key

My Wish

- I wish we could tell Spring:

Create a DAO for me

Plug in my entity type and primary key

Give me all of the basic CRUD features for free

My Wish Diagram

Spring Data JPA - Solution

- Spring Data JPA is the solution!!!!

<https://spring.io/projects/spring-data-jpa>

- Create a DAO and just plug in your entity type and primary key
- Spring will give you a CRUD implementation for FREE like MAGIC!!
- Helps to minimize boiler-plate DAO code ... yaaay!!!

More than 70% reduction in code ... depending on use case

JpaRepository

- Spring Data JPA provides the interface: **JpaRepository**
- Exposes methods (some by inheritance from parents)

Entity: Employee

Primary key: Integer

`findAll()`
`findById(...)`
`save(...)`
`deleteById(...)`
... others ...

Development Process

Step-By-Step

1. Extend **JpaRepository** interface
2. Use your Repository in your app

No need for
implementation class

Step 1: Extend JpaRepository interface

Entity type

Primary key

```
public interface EmployeeRepository extends JpaRepository<Employee, Integer> {  
  
    // that's it ... no need to write any code LOL!  
  
}
```

No need for
implementation class

Get these
methods for free

Entity: Employee

Primary key: Integer

findAll()
findById(...)
save(...)
deleteById(...)
... others ...

JpaRepository Docs

- Full list of methods available ... see JavaDoc for **JpaRepository**

www.luv2code.com/jpa-repository-javadoc

Step 2: Use Repository in your app

```
@Service
public class EmployeeServiceImpl implements EmployeeService {

    private EmployeeRepository employeeRepository;

    @Autowired
    public EmployeeServiceImpl(EmployeeRepository theEmployeeRepository) {
        employeeRepository = theEmployeeRepository;
    }

    @Override
    public List<Employee> findAll() {
        return employeeRepository.findAll();
    }
    ...
}
```

Our repository

Magic method that is available via repository

Minimized Boilerplate Code

Before Spring Data JPA

```
public interface EmployeeDAO {  
    public List<Employee> findAll();  
    public Employee findById(int theId);  
    public void save(Employee theEmployee);  
    public void delete(int theId);  
}
```

```
@Repository  
public class EmployeeDAOJpaImpl implements EmployeeDAO {  
    private EntityManager em;  
    @Autowired  
    public EmployeeDAOJpaImpl(EntityManager theEntityManager) {  
        em = theEntityManager;  
    }  
    @Override  
    public List<Employee> findAll() {  
        // create TypedQuery  
        TypedQuery<Employee> query = em.createQuery("select e from Employee e", Employee.class);  
        // execute query  
        List<Employee> results = query.getResultList();  
        // return results  
        return results;  
    }  
    @Override  
    public Employee findById(int theId) {  
        // get employee  
        Employee theEmployee = em.find(Employee.class, theId);  
        // return employee  
        return theEmployee;  
    }  
}
```

**2 Files
30+ lines of code**

After Spring Data JPA

```
public interface EmployeeRepository extends JpaRepository<Employee, Integer> {  
    // that's it ... no need to write any code LOL!  
}
```

**1 File
3 lines of code!**

**No need for
implementation class**

Advanced Features

- Advanced features available for
 - Extending and adding custom queries with JPQL
 - Query Domain Specific Language (Query DSL)
 - Defining custom methods (low-level coding)

www.luv2code.com/spring-data-jpa-defining-custom-queries

Spring Data REST in Spring Boot

Spring Data JPA

- Earlier, we saw the magic of Spring Data JPA
- This helped to eliminate boilerplate code

Before Spring Data JPA

```
public interface EmployeeDAO {  
    public List<Employee> findAll();  
    public Employee findById(int theId);  
    public void save(Employee theEmployee);  
    public void delete(int theId);  
}
```

```
@Repository  
public class EmployeeDAOImpl implements EmployeeDAO {  
    private EntityManager em;  
    @Autowired  
    public EmployeeDAOImpl(EntityManager em) {  
        this.em = em;  
    }  
    @Override  
    public List<Employee> findAll() {  
        // create TypedQuery  
        TypedQuery<Employee> query = em.createQuery("select e from Employee e", Employee.class);  
        // return employee  
        return query.getResultList();  
    }  
    @Override  
    public Employee findById(int theId) {  
        // get employee  
        Employee theEmployee = em.find(Employee.class, theId);  
        // return employee  
        return theEmployee;  
    }  
}
```

2 Files
30+ lines of code

After Spring Data JPA

```
public interface EmployeeRepository extends JpaRepository<Employee, Integer> {  
    // that's it ... no need to write any code LOL!  
}
```

1 File
3 lines of code!

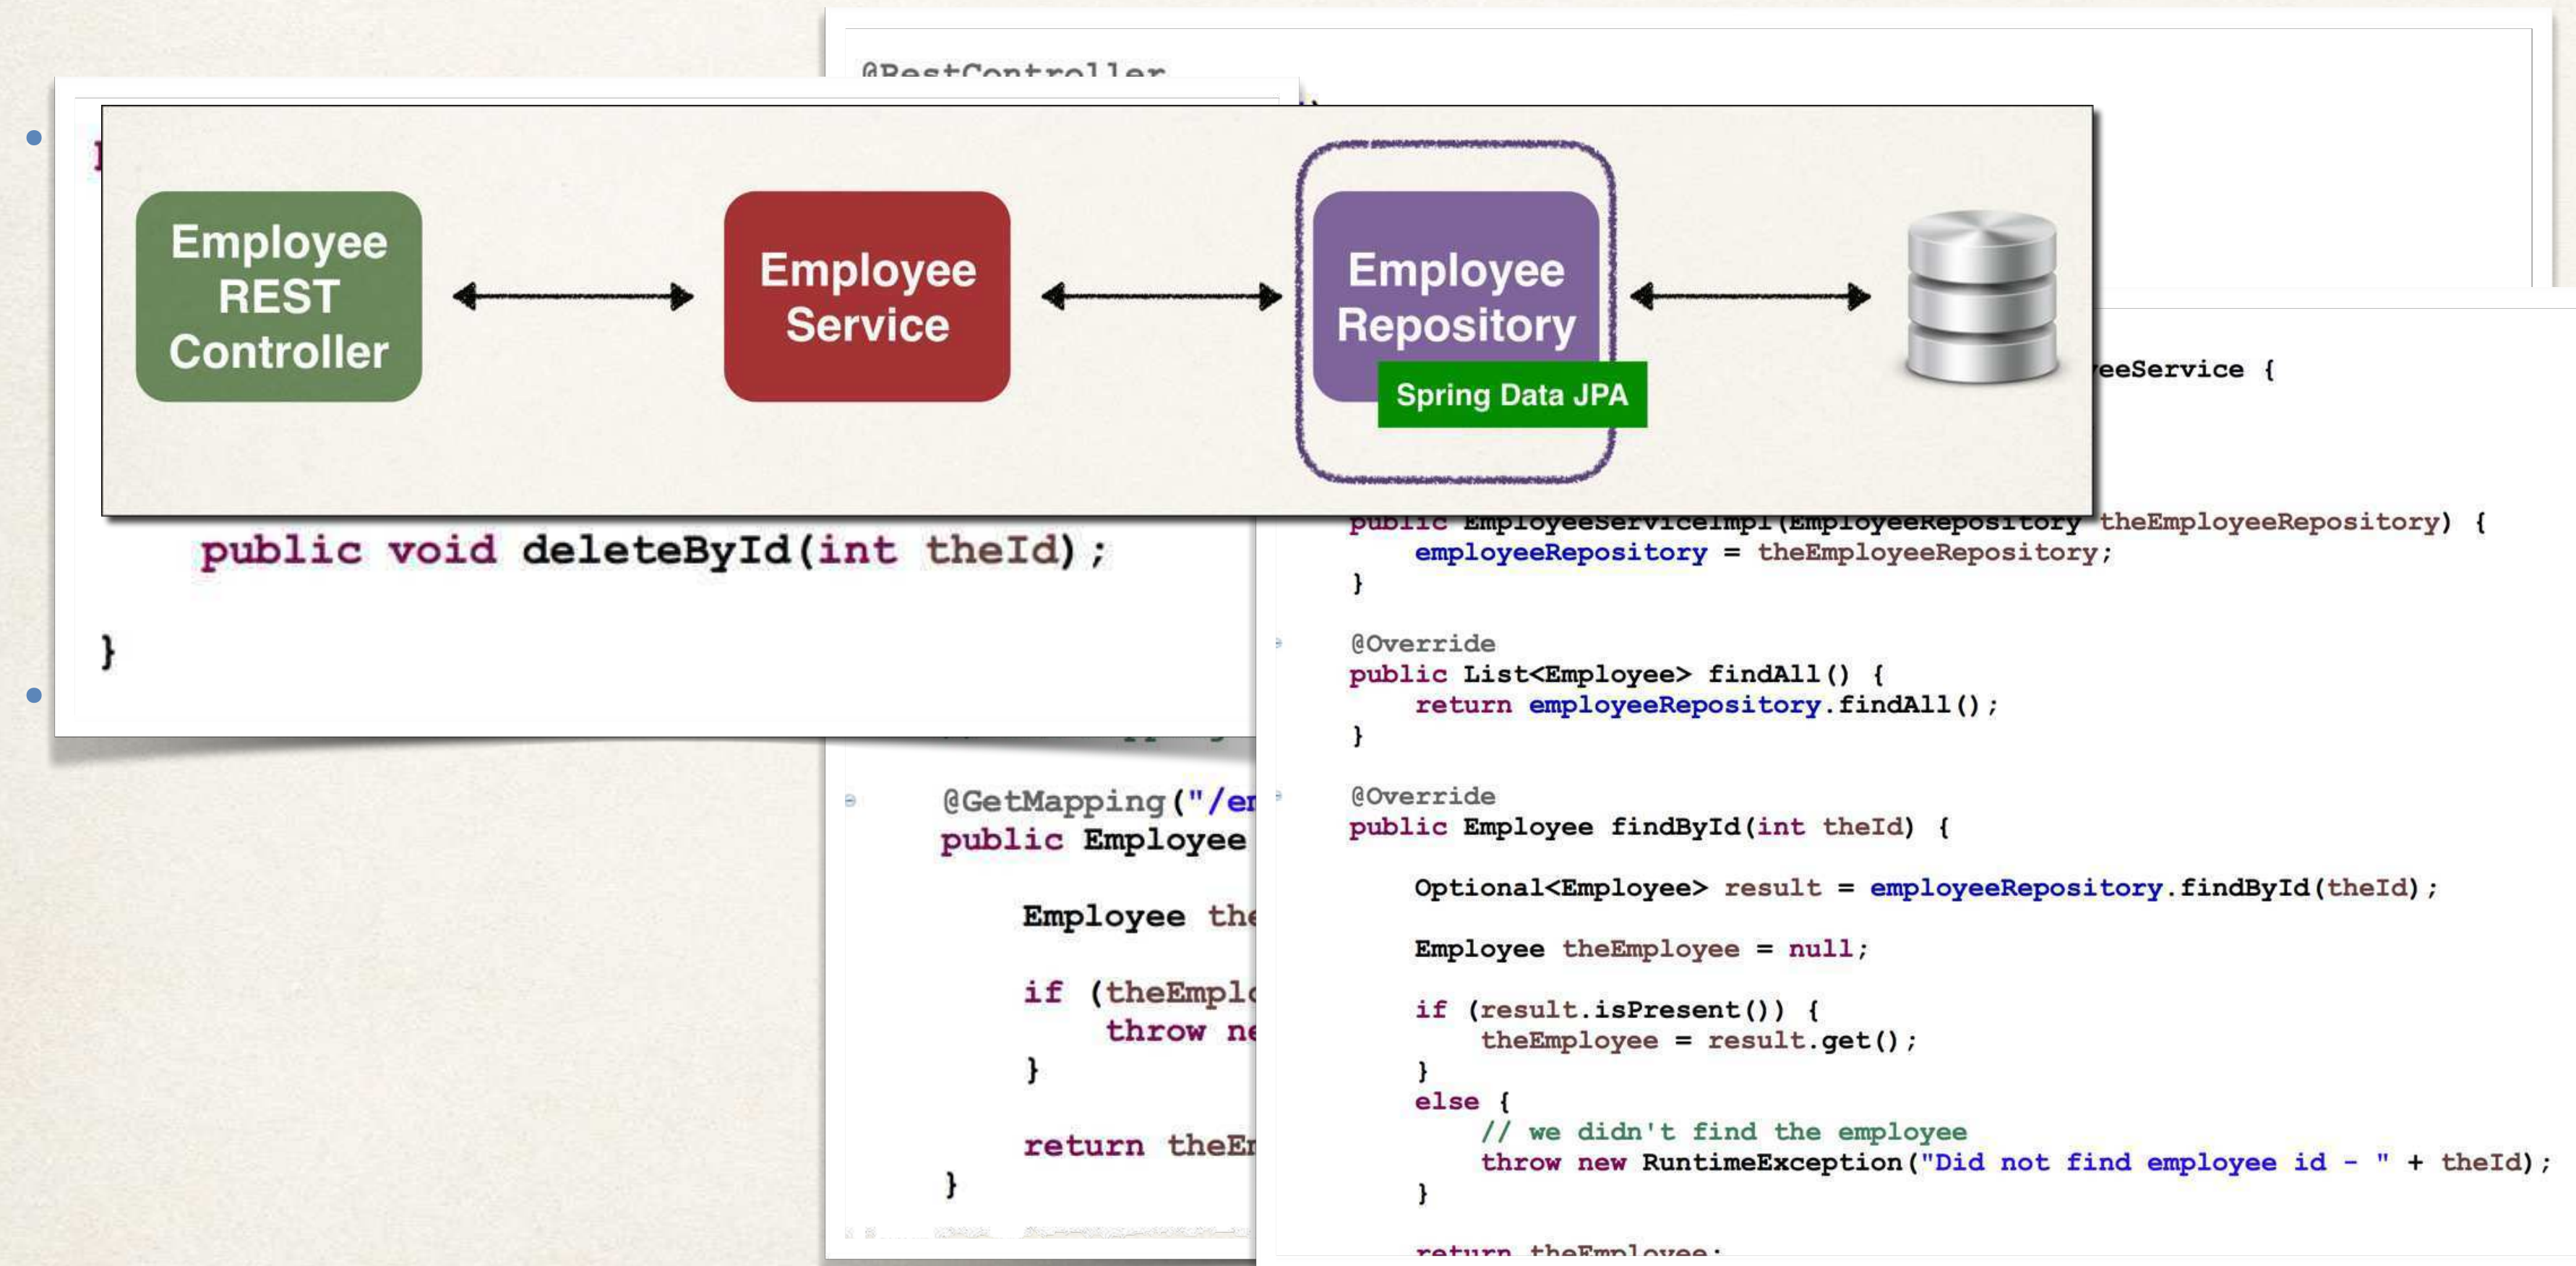

No need for
implementation class

Hmmm ...
Can this apply to REST APIs?

The Problem

- We saw how to create a REST API for **Employee**

My Wish

- I wish we could tell Spring:

Create a REST API for me

Use my existing JpaRepository (entity, primary key)

Give me all of the basic REST API CRUD features for free

Spring Data REST - Solution

- Spring Data REST is the solution!!!!

<https://spring.io/projects/spring-data-rest>

- Leverages your existing **JpaRepository**
- Spring will give you a REST CRUD implementation for FREE like MAGIC!!
- Helps to minimize boiler-plate REST code!!!
- No new coding required!!!

Spring Data REST - How Does It Work?

- Spring Data REST will scan your project for **JpaRepository**
- Expose REST APIs for each entity type for your **JpaRepository**

```
public interface EmployeeRepository extends JpaRepository<Employee, Integer> {  
  
}
```

REST Endpoints

- By default, Spring Data REST will create endpoints based on entity type
- Simple pluralized form
 - First character of Entity type is lowercase
 - Then just adds an "s" to the entity

*More on
plural forms in
later video*

```
public interface EmployeeRepository extends JpaRepository<Employee, Integer> {  
}
```

/employees

Development Process

Step-By-Step

1. Add Spring Data REST to your Maven POM file

That's it!!!

Absolutely NO CODING required

Step 1: Add Spring Data REST to POM file

```
<dependency>
  <groupId>org.springframework.boot</groupId>
  <artifactId>spring-boot-starter-data-rest</artifactId>
</dependency>
```

That's it!!!

Absolutely NO CODING required

**Spring Data REST will
scan for JpaRepository**

HTTP Method		CRUD Action
POST	/employees	<u>C</u> reate a new employee
GET	/employees	<u>R</u> ead a list of employees
GET	/employees/{employeeId}	<u>R</u> ead a single employee
PUT	/employees/{employeeId}	<u>U</u> pdate an existing employee
DELETE	/employees/{employeeId}	<u>D</u> delete an existing employee

Get these REST
endpoints for free

In A Nutshell

For Spring Data REST, you only need 3 items

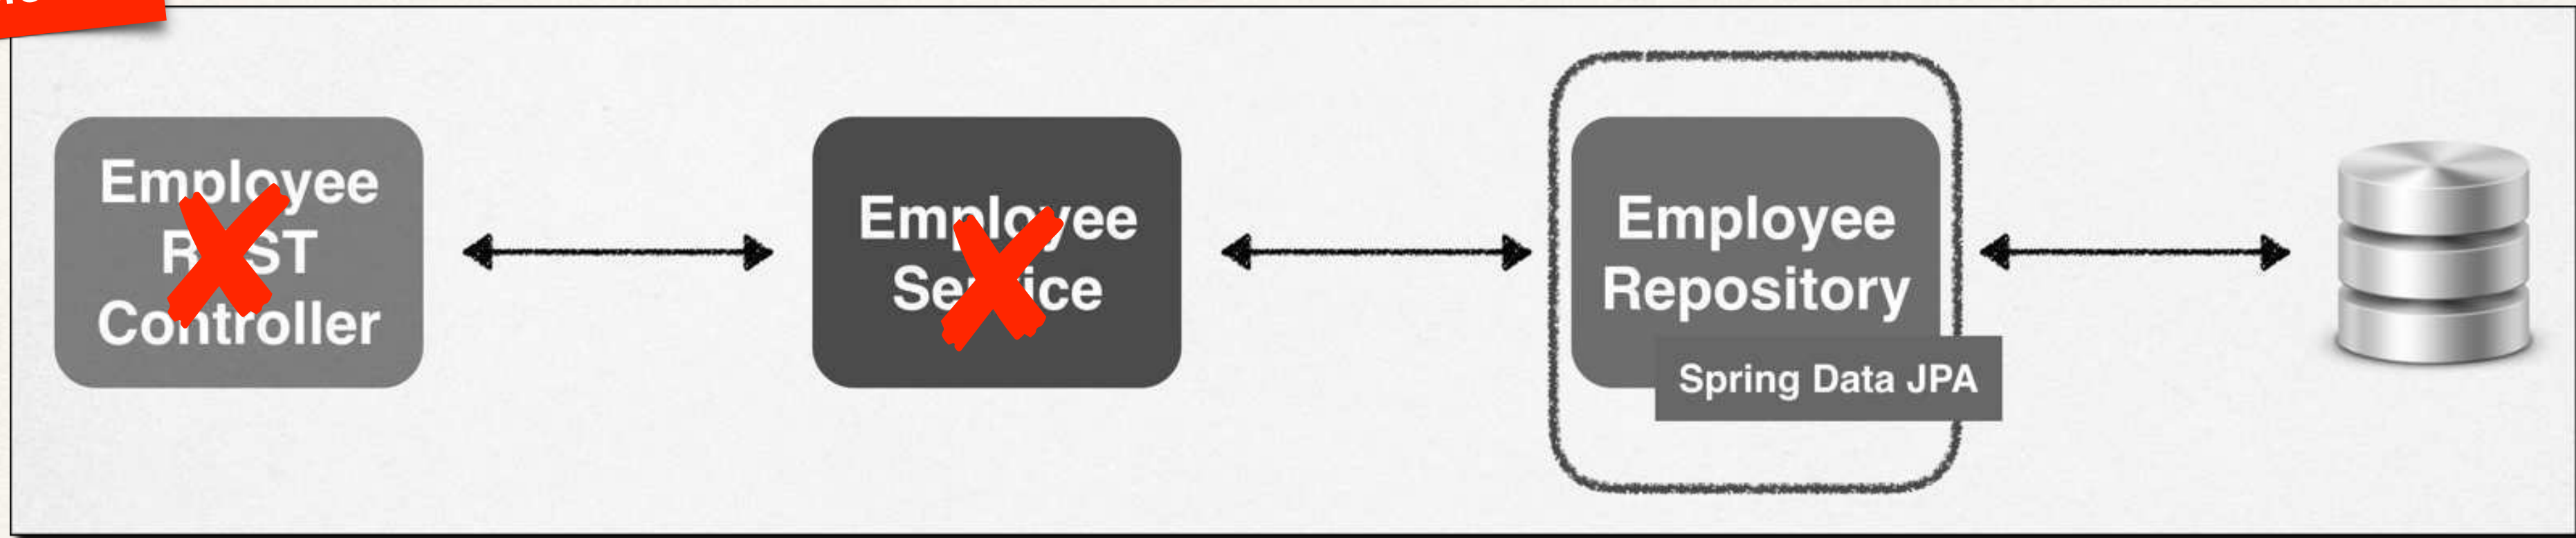

We already have these two

1. Your entity: **Employee**
2. JpaRepository: **EmployeeRepository** extends **JpaRepository**
3. Maven POM dependency for: **spring-boot-starter-data-rest**

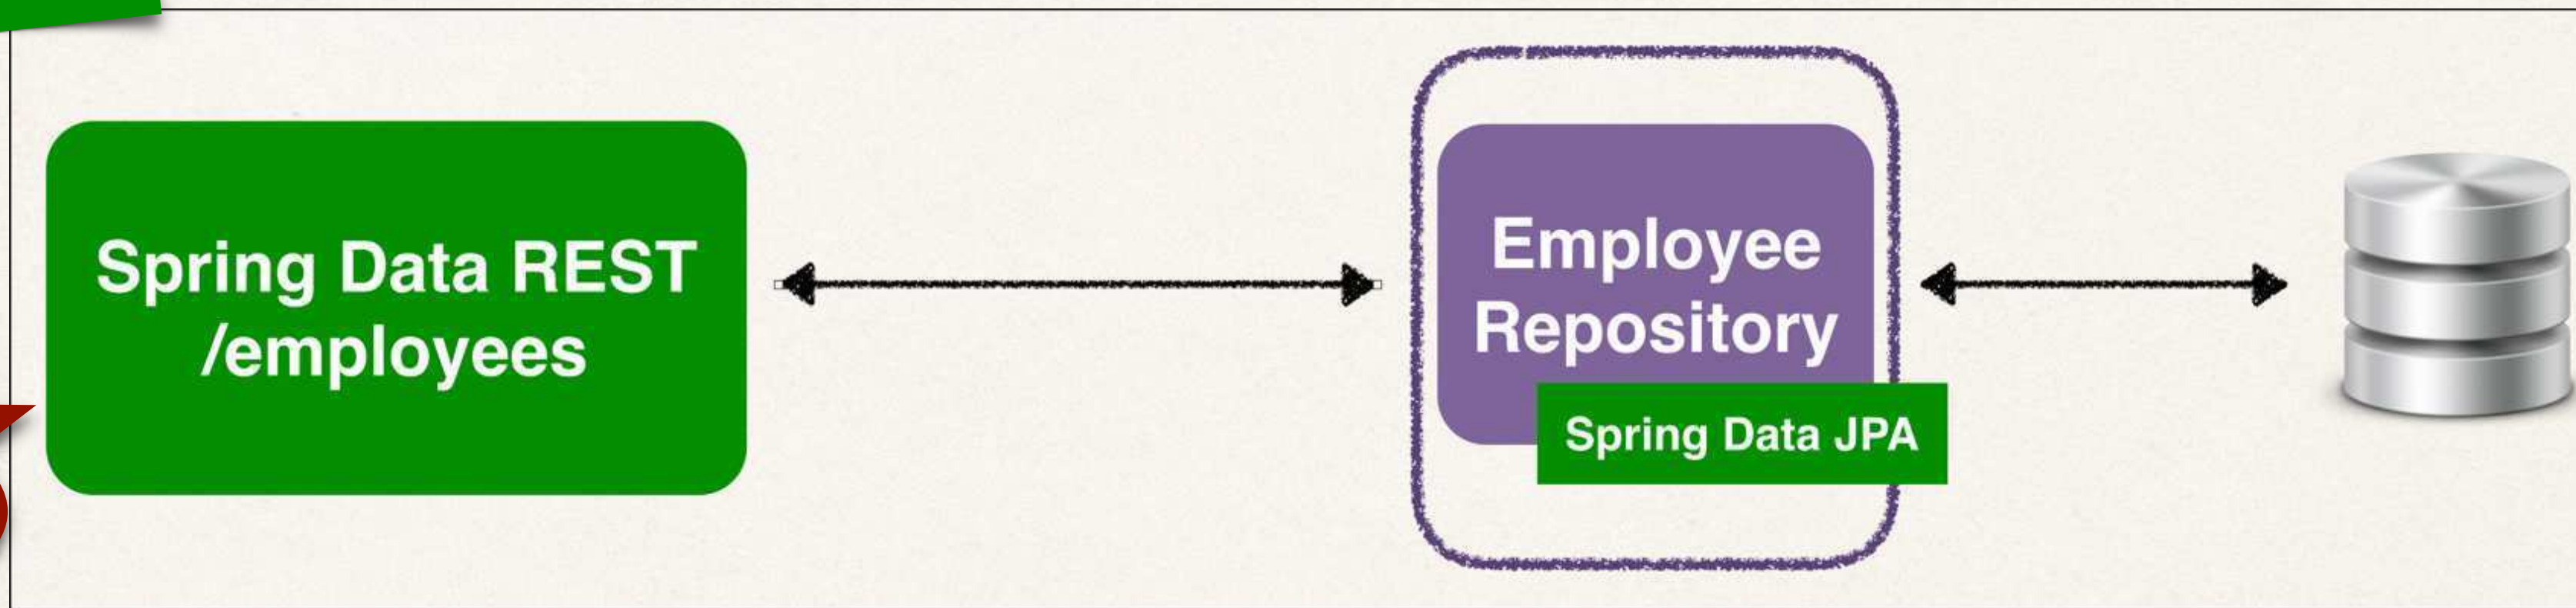

Only item that is new

Application Architecture

Before

After

Get these REST endpoints for free

Minimized Boilerplate Code

Before Spring Data REST

```
@RestController
@RequestMapping("/api")
public class EmployeeRestController {

    private EmployeeService employeeService;

    @Autowired
    public EmployeeRestController(EmployeeService theEmployeeService) {
        employeeService = theEmployeeService;
    }

    // expose "/employees" and return list of
    @GetMapping("/employees")
    public List<Employee> findAll() {
        return employeeService.findAll();
    }

    // add mapping for GET /employees/{id}
    @GetMapping("/employees/{id}")
    public Employee getEmployeeById(int theId) {
        Employee theEmployee = employeeService.findById(theId);

        if (theEmployee == null) {
            throw new RuntimeException("Employee not found - " + theId);
        }

        return theEmployee;
    }
}
```

```
public interface EmployeeService {

    List<Employee> findAll();

    Employee findById(int theId);

    Employee findByIdAndName(String theId, String theName);
}

public class EmployeeServiceImpl implements EmployeeService {

    private EmployeeRepository employeeRepository;

    @Autowired
    public EmployeeServiceImpl(EmployeeRepository theEmployeeRepository) {
        employeeRepository = theEmployeeRepository;
    }

    @Override
    public List<Employee> findAll() {
        return employeeRepository.findAll();
    }

    @Override
    public Employee findById(int theId) {
        Employee result = employeeRepository.findById(theId);

        if (result == null) {
            throw new RuntimeException("Employee not found - " + theId);
        }

        return result;
    }

    @Override
    public Employee findByIdAndName(String theId, String theName) {
        Employee result = employeeRepository.findByIdAndName(theId, theName);

        if (result == null) {
            throw new RuntimeException("Employee not found - " + theId);
        }

        return result;
    }
}
```

```
public class Employee {

    private int id;
    private String name;

    // getters and setters
}
```

3 files
100+ lines of code

After Spring Data REST

```
<dependency>
  <groupId>org.springframework.boot</groupId>
  <artifactId>spring-boot-starter-data-rest</artifactId>
</dependency>
```

That's it!!!

Absolutely NO CODING required

HTTP Method	Endpoint	CRUD Action
POST	/employees	Create a new employee
GET	/employees	Read a list of employees
GET	/employees/{employeeId}	Read a single employee
PUT	/employees/{employeeId}	Update an existing employee
DELETE	/employees/{employeeId}	Delete an existing employee

Spring Data REST will scan for JpaRepository

Get these REST endpoints for free

HATEOAS

- Spring Data REST endpoints are HATEOAS compliant
- **HATEOAS:** Hypermedia as the Engine of Application State
- Hypermedia-driven sites provide information to access REST interfaces
- Think of it as meta-data for REST data

<https://spring.io/projects/spring-hateoas>

HATEOAS

- Spring Data REST response using HATEOAS
- For example REST response from: **GET /employees/3**

Get single
employee

Response

```
{
  "firstName": "Avani",
  "lastName": "Gupta",
  "email": "avani@luv2code.com",
  "_links": {
    "self": {
      "href": "http://localhost:8080/employees/3"
    },
    "employee": {
      "href": "http://localhost:8080/employees/3"
    }
  }
}
```

Employee data

Response meta-data
Links to data

HATEOAS

- For a collection, meta-data includes page size, total elements, pages etc
- For example REST response from: **GET /employees**

Get list of employees

Response

```
{
  "_embedded": {
    "employees": [
      {
        "firstName": "Leslie",
        ...
      },
      ...
    ]
  },
  "page": {
    "size": 20,
    "totalElements": 5,
    "totalPages": 1,
    "number": 0
  }
}
```

JSON Array of employees

Response meta-data
Information about the page

*More on
configuring page
sizes later*

HATEOAS

- For details on HATEOAS, see

<https://spring.io/projects/spring-hateoas>

- HATEOAS uses Hypertext Application Language (HAL) data format
- For details on HAL, see

https://en.wikipedia.org/wiki/Hypertext_Application_Language

Advanced Features

- Spring Data REST advanced features
 - Pagination, sorting and searching
 - Extending and adding custom queries with JPQL
 - Query Domain Specific Language (Query DSL)

<https://spring.io/projects/spring-data-rest>

Spring Data REST Configuration, Pagination and Sorting

REST Endpoints

- By default, Spring Data REST will create endpoints based on entity type
- Simple pluralized form
 - First character of Entity type is lowercase
 - Then just adds an "s" to the entity

```
public interface EmployeeRepository extends JpaRepository<Employee, Integer> {  
}
```

/employees

Pluralized Form

- Spring Data REST pluralized form is VERY simple
 - Just adds an "s" to the entity
- The English language is VERY complex!
 - Spring Data REST does NOT handle

Singular	Plural
Goose	Geese
Person	People
Syllabus	Syllabi
...	...

Problem

- Spring Data REST does not handle complex pluralized forms
 - In this case, you need to specify plural name
- What if we want to expose a different resource name?
 - Instead of **/employees** ... use **/members**

Solution

- Specify plural name / path with an annotation

```
@RepositoryRestResource(path="members")  
public interface EmployeeRepository extends JpaRepository<Employee, Integer> {  
}
```

<http://localhost:8080/members>

Pagination

- By default, Spring Data REST will return the first 20 elements
 - Page size = 20
- You can navigate to the different pages of data using query param

```
http://localhost:8080/employees?page=0
```

```
http://localhost:8080/employees?page=1
```

```
...
```

**Pages are
zero-based**

Spring Data REST Configuration

- Following properties available: application.properties

Name	Description
<code>spring.data.rest.base-path</code>	Base path used to expose repository resources
<code>spring.data.rest.default-page-size</code>	Default size of pages
<code>spring.data.rest.max-page-size</code>	Maximum size of pages
...	...

More properties available
www.luv2code.com/spring-boot-props

`spring.data.rest.*`

Sample Configuration

<http://localhost:8080/magic-api/employees>

File: application.properties

```
spring.data.rest.base-path=/magic-api  
spring.data.rest.default-page-size=50
```

Returns 50
elements per page

Documenting REST APIs with OpenAPI and Swagger

The Problem

- There is a REST API out there ... but we don't have any documentation
- We have to review the source code to find endpoints: @GetMapping etc
- Then use Postman or curl to call the REST API

```
public class EmployeeRestController {  
  
    // expose "/employees" and return a list of employees  
    @GetMapping("/employees") no usages  
    public List<Employee> findAll() { return employeeService.findAll(); }  
  
    // add mapping for GET /employees/{employeeId}  
  
    @GetMapping("/employees/{employeeId}") no usages  
    public Employee getEmployee(@PathVariable int employeeId) {  
  
        Employee theEmployee = employeeService.findById(employeeId);  
  
        if (theEmployee == null) {  
            throw new RuntimeException("Employee id not found - " + employeeId);  
        }  
  
        return theEmployee;  
    }  
}
```

My Wish

- I wish we could tell our app:

At run-time, generate API documentation

*Inspect API endpoints based on
Spring Configs, annotations etc*

*Provide a web UI for accessing endpoints
No need for Postman*

Springdoc To The Rescue

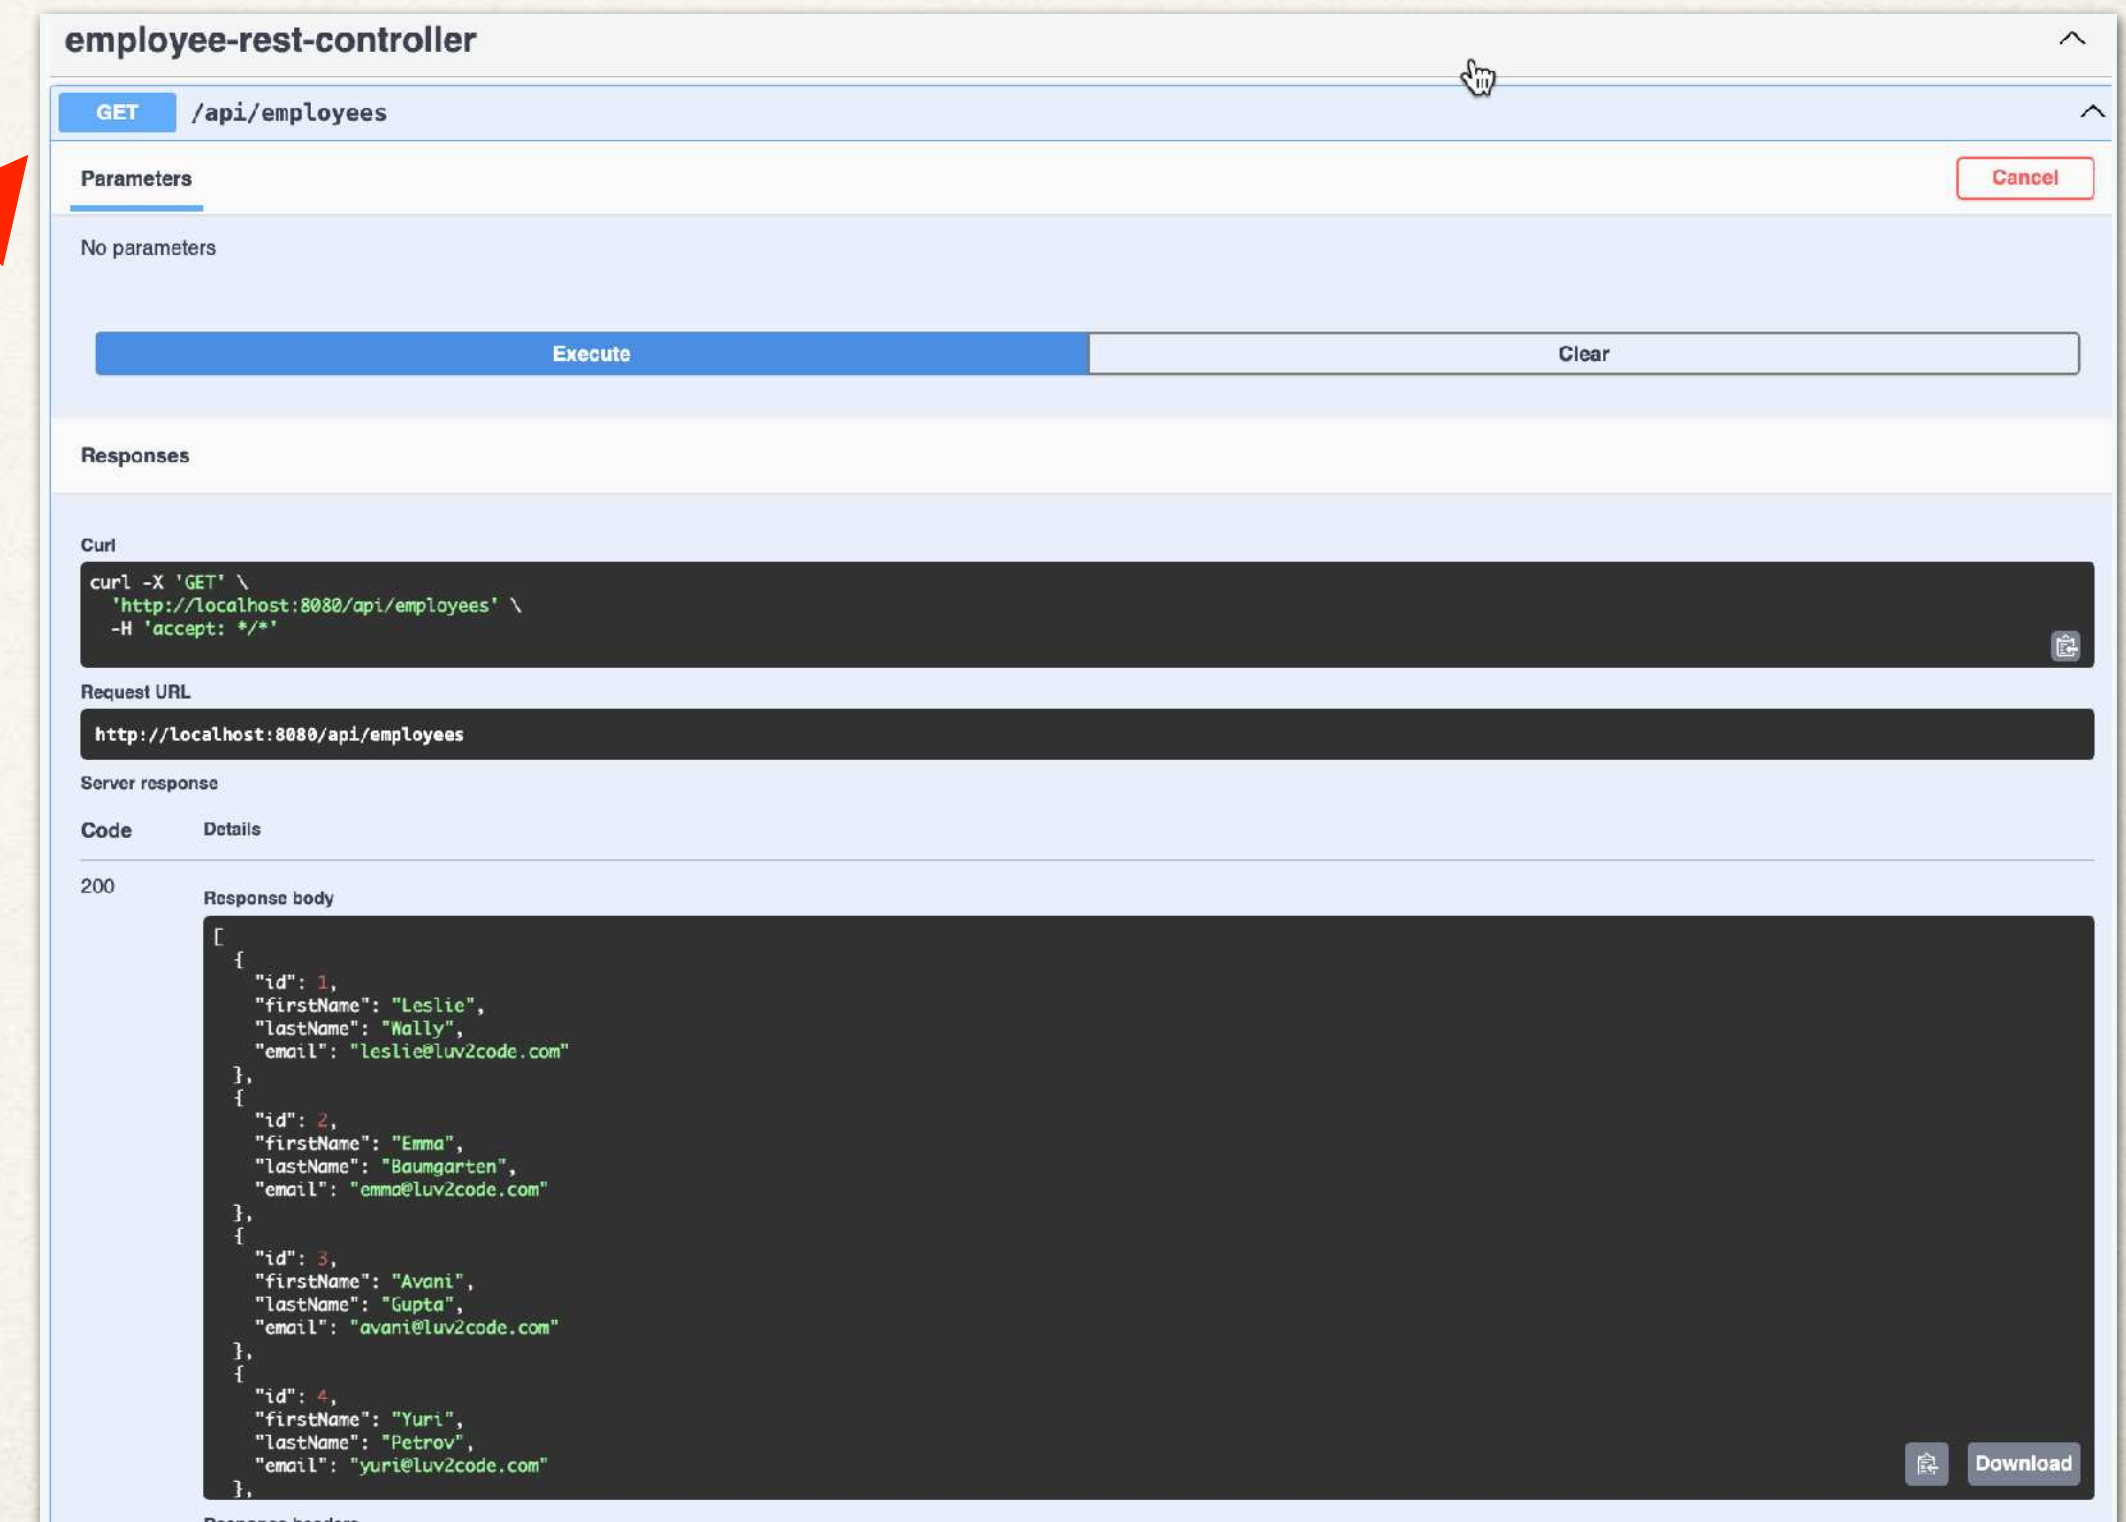

www.springdoc.org

- **Springdoc** is separate open-source project
- Generates API documentation
- Inspects API endpoints based on Spring Configs, annotations etc
- Provides a web UI for accessing endpoints
 - No need for Postman

Springdoc - Swagger Web UI

www.springdoc.org

- Springdoc provides a **Swagger** web UI for accessing endpoints

Documenting REST APIs

www.springdoc.org

- OpenAPI is an industry standard format for documenting APIs
 - www.openapis.org
- **Swagger UI** is a browser-based UI for interacting with your API
 - Powered by Springdoc-OpenAPI

Development Process

Step-By-Step

1. Add Maven dependency for Springdoc
2. Access Swagger UI
3. Retrieve API endpoints as JSON or YAML

Step 1: Add Maven dependency for Springdoc

```
<dependency>  
  <groupId>org.springdoc</groupId>  
  <artifactId>springdoc-openapi-starter-webmvc-ui</artifactId>  
  <version>x.y.z</version>  
</dependency>
```

www.springdoc.org

Step 2: Access the Swagger UI

- By default, Swagger UI is available at:
- `http://localhost:8080/swagger-ui/index.html`

Configure Custom Path for Swagger UI

- Can configure a custom path in application.properties

```
# configure custom path  
springdoc.swagger-ui.path=/my-fun-ui.html
```

- Access Swagger UI at
 - `http://localhost:8080/my-fun-ui.html`

Step 3: Retrieve API endpoints as JSON or YAML

- Docs for API endpoints available as JSON or YAML
- Useful for integration with other development tools
- Client SDK generation, API mocking, contract testing, etc
- JSON or YAML is language independent
- Can be processed by Python, Javascript, Go, C# etc

Step 3: Retrieve API endpoints as JSON or YAML

- By default, JSON docs available here
- <http://localhost:8080/v3/api-docs>

```
{
  "openapi": "3.1.0",
  "info": {
    "title": "OpenAPI definition",
    "version": "v0"
  },
  "servers": [
    {
      "url": "http://localhost:8080",
      "description": "Generated server url"
    }
  ],
  "paths": {
    "/api/employees": {
      "get": {
        "tags": [
          "employee-rest-controller"
        ],
        "operationId": "findAll",
        "responses": {
          "200": {
            "description": "OK",
            "content": {
              "*/*": {
                "schema": {
                  "type": "array",
                  "items": {
                    "$ref": "#/components/schemas/Employee"
                  }
                }
              }
            }
          }
        }
      }
    }
  }
}
```

Step 3: Retrieve API endpoints as JSON or YAML

- YAML docs available here
 - <http://localhost:8080/v3/api-docs.yaml>
- Web browser will download the YAML file
- You can view it with any text editor

```
! api-docs.yaml x
Users > chaddarby > Downloads > ! api-docs.yaml > openapi
1 openapi: 3.1.0
2 info:
3   title: OpenAPI definition
4   version: v0
5 servers:
6   - url: http://localhost:8080
7     description: Generated server url
8 paths:
9   /api/employees:
10    get:
11      tags:
12        - employee-rest-controller
13      operationId: findAll
14      responses:
15        "200":
16          description: OK
17          content:
18            '*/*':
19              schema:
20                type: array
21                items:
22                  $ref: "#/components/schemas/Employee"
23      put:
24      tags:
```

Configure Custom Path for API docs

- Can configure a custom path in application.properties

```
# configure custom path  
springdoc.api-docs.path=/my-api-docs
```

- Access API Docs at

- <http://localhost:8080/my-api-docs>

JSON

- <http://localhost:8080/my-api-docs.yaml>

YAML

Spring Data REST with OpenAPI and Swagger

**Can I use OpenAPI and Swagger UI
with Spring Data REST???**

Yes!
Use the same development process

Development Process

Step-By-Step

1. Add Maven dependency for Springdoc
2. Access Swagger UI
3. Retrieve API endpoints as JSON or YAML

Sorting

- You can sort by the property names of your entity
 - In our Employee example, we have: **firstName**, **lastName** and **email**
- Sort by last name (ascending is default) <http://localhost:8080/employees?sort=lastName>
- Sort by first name, descending <http://localhost:8080/employees?sort=firstName,desc>
- Sort by last name, then first name, ascending <http://localhost:8080/employees?sort=lastName,firstName,asc>
